## Chapter 1

## Introduction

This book presents examples and case studies on how to use R for data mining applications.

This chapter introduces some basic concepts and techniques for data mining, including a data mining procedure and popular data mining techniques, such as clustering, classification and association rules. It also presents R and its packages, functions and task views for data mining. At last, some datasets used in this book are described.

### 1.1 Data Mining

Data mining is ....

The main techniques for data mining are listed below. More detailed introduction can be found in text books on data mining [Han and Kamber, 2000, Hand et al., 2001, Witten and Frank, 2005].

- Clustering:
- Classification:
- Association Rules:
- Sequential Patterns:
- Time Series Analysis:
- Text Mining:

### 1.2 R

R  $^1$  [R Development Core Team, 2012] is a free software environment for statistical computing and graphics. It provides a wide variety of statistical and graphical techniques. R can be extended easily via packages. There are more than 3000 packages available in the CRAN package repository  $^2$ , as on May 20, 2011. More details about R are available in An Introduction to R  $^3$  [Venables et al., 2010] and R Language Definition  $^4$  [R Development Core Team, 2010b].

R is widely used in academia and research, as well as industrial applications.

### 1.2.1 R Packages and Functions for Data Mining

A collection of R packages and functions available for data mining are listed below. Some of them are not specially for data mining, but they are included here because they are useful in data mining applications.

### 1. Clustering

- Packages:
  - fpc
  - cluster
  - pvclust
  - mclust
- Partitioning-based clustering: kmeans, pam, pamk, clara
- Hierarchical clustering: hclust, pvclust, agnes, diana
- Model-based clustering: mclust
- Density-based clustering: dbscan
- Plotting cluster solutions: plotcluster, plot.hclust
- Validating cluster solutions: cluster.stats

### 2. Classification

- Packages:
  - rpart
  - party
  - randomForest
  - rpartOrdinal
  - tree
  - margin Tree
  - maptree
  - survival
- Decision trees: rpart, ctree
- Random forest: cforest, randomForest
- Regression, Logistic regression, Poisson regression: glm, predict, residuals
- Survival analysis: survfit, survdiff, coxph
- 3. Association Rules and Frequent Itemsets
  - Packages:
    - arules: supports to mine frequent itemsets, maximal frequent itemsets, closed frequent itemsets and association rules
    - $-\ drm$ : regression and association models for repeated categorical data
  - APRIORI algorithm, a level-wise, breadth-first algorithm which counts transactions: apriori, drm
  - ECLAT algorithm: employs equivalence classes, depth-first search and set intersection instead of counting: eclat

### 4. Sequential Patterns

• Package: arulesSequences

1.3. DATASETS 3

- SPADE algorithm: cSPADE
- 5. Time Series
  - Package: timsac
  - Time series construction: ts
  - Decomposition: decomp, decompose, stl, tsr
- 6. Statistics
  - Package: Base R, nlme
  - Analysis of Variance: aov, anova
  - Density analysis: density
  - Statistical test: t.test, prop.test, anova, aov
  - Linear mixed-effects model fit: 1me
  - Principal components and factor analysis: princomp
- 7. Graphics
  - Bar chart: barplot
  - Pie chart: pie
  - Scattered plot: dotchart
  - Histogram: hist
  - Density: densityplot
  - Candlestick chart, box plot: boxplot
  - QQ (quantile-quantile) plot: qqnorm, qqplot, qqline
  - Bi-variate plot: coplot
  - Tree: rpart
  - Parallel coordinates: parallel, paracoor, parcoord
  - Heatmap, contour: contour, filled.contour
  - Other plots: stripplot, sunflowerplot, interaction.plot, matplot, fourfold-plot, assocplot, mosaicplot
  - Saving graphs: pdf, postscript, win.metafile, jpeg, bmp, png
- 8. Data Manipulation
  - Missing values: na.omit
  - Standardize variables: scale
  - Transpose: t
  - Sampling: sample
  - Stack: stack, unstack
  - Others: aggregate, merge, reshape
- 9. Interface to Weka
  - RWeka: an R/Weka interface enabling to use all Weka functions in R.

### 1.3 Datasets

The datasets used in this book.

#### 1.3.1 Iris Dataset

Iris dataset consists of 50 samples from each of three classes of iris flowers [Frank and Asuncion, 2010]. One class is linearly separable from the other two, while the latter are not linearly separable from each other. There are five attributes in the dataset:

- sepal length in cm,
- sepal width in cm,
- petal length in cm,
- petal width in cm, and
- class: Iris Setosa, Iris Versicolour, and Iris Virginica.

#### > str(iris)

```
'data.frame': 150 obs. of 5 variables:

$ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...

$ Sepal.Width: num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...

$ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...

$ Petal.Width: num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...

$ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 ...
```

### 1.3.2 Bodyfat Dataset

Bodyfat is a dataset available in package *mboost* [Hothorn et al., 2012]. It has 71 rows, which each row contains information of one person. It contains the following 10 numeric columns.

- age: age in years.
- DEXfat: body fat measured by DXA, response variable.
- waistcirc: waist circumference.
- hipcirc: hip circumference.
- elbowbreadth: breadth of the elbow.
- kneebreadth: breadth of the knee.
- anthro3a: sum of logarithm of three anthropometric measurements.
- anthro3b: sum of logarithm of three anthropometric measurements.
- anthro3c: sum of logarithm of three anthropometric measurements.
- anthro4: sum of logarithm of three anthropometric measurements.

The value of DEXfat is to be predicted by the other variables.

1.3. DATASETS 5

```
$ kneebreadth : num 9.4 8.9 8.9 9.2 10 8.8 8.9 8.5 8.8 8.8 ...
```

\$ anthro3a : num 4.42 4.63 4.12 4.03 4.24 3.55 4.14 4.04 3.91 3.66 ... \$ anthro3b : num 4.95 5.01 4.74 4.48 4.68 4.06 4.52 4.7 4.32 4.21 ... \$ anthro3c : num 4.5 4.48 4.6 3.91 4.15 3.64 4.31 4.47 3.47 3.6 ... \$ anthro4 : num 6.13 6.37 5.82 5.66 5.91 5.14 5.69 5.7 5.49 5.25 ...

## Chapter 2

## Data Import/Export

This chapter shows how to import data into R and how to export R data frames. For more details, please refer to R Data Import/Export  $^1$  [R Development Core Team, 2010a].

### 2.1 Save/Load R Data

Data in R can be saved as .Rdata files with functions save. After that, they can then be loaded into R with load.

```
> a <- 1:10
> save(a, file = "data/dumData.Rdata")
> rm(a)
> load("data/dumData.Rdata")
> print(a)

[1] 1 2 3 4 5 6 7 8 9 10
```

## 2.2 Import from and Export to .CSV Files

The example below creates a dataframe a and save it as a .CSV file with write.csv. And then, the dataframe is loaded from file to variable b with read.csv.

```
> var1 <- 1:5
> var2 <- (1:5) / 10
> var3 <- c("R", "and", "Data Mining", "Examples", "Case Studies")
> a <- data.frame(var1, var2, var3)</pre>
> names(a) <- c("VariableInt", "VariableReal", "VariableChar")
> write.csv(a, "data/dummmyData.csv", row.names = FALSE)
> b <- read.csv("data/dummmyData.csv")</pre>
> print(b)
  VariableInt VariableReal VariableChar
1
            1
                        0.1
3
            3
                        0.3
                             Data Mining
4
            4
                        0.4
                                Examples
5
                        0.5 Case Studies
```

http://cran.r-project.org/doc/manuals/R-data.pdf

### 2.3 Import Data from SAS

Package foreign provides function read.ssd for importing SAS datasets (.sas7bdat files) into R. However, the following points are essential to make importing successful.

- SAS must be available on your computer, and read.ssd will call SAS to read SAS datasets and import them into R.
- The file name of a SAS dataset has to be no longer than eight characters. Otherwise, the importing would fail. There is no such a limit when importing from a .CSV file.
- During importing, variable names longer than eight characters are truncated to eight characters, which often makes it difficult to know the meanings of variables. One way to get around this issue is to import variable names separately from a .CSV file, which keeps full names of variables.

An empty .CSV file with variable names can be generated with the following method.

1. Create an empty SAS table dumVariables from dumData as follows.

```
data work.dumVariables;
   set work.dumData(obs=0);
run;
```

2. Export table dumVariables as a .CSV file.

The example below demonstrates importing data from a SAS dataset. Assume that there is a SAS data file dumData.sas7bdat and a .CSV file dumVariables.csv in folder "Current working directory/data".

```
1 1 0.1 R
2 2 0.2 and
3 3 0.3 Data Mining
4 4 0.4 Examples
5 5 0.5 Case Studies
```

Note that the variable names above are truncated. The full names are imported from a .CSV file with the following code.

```
> variableFileName <- "dumVariables.csv"</pre>
> myNames <- read.csv(paste(filepath, variableFileName, sep="/"))
> names(a) <- names(myNames)</pre>
> print(a)
  VariableInt VariableReal VariableChar
1
                        0.1
            1
                                         R.
            2
                        0.2
2
                                       and
3
            3
                        0.3 Data Mining
4
            4
                        0.4
                                 Examples
5
            5
                        0.5 Case Studies
```

Although one can export a SAS dataset to a .CSV file and then import data from it, there are problems when there are special formats in the data, such as a value of "\$100,000" for a numeric variable. In this case, it would be better to import from a .sas7bdat file. However, variable names may need to be imported into R separately.

Another way to import data from a SAS dataset is to use function read.xport to read a file in SAS Transport (XPORT) format.

### 2.4 Import/Export via ODBC

Package RODBC provides connection to ODBC databases.

#### 2.4.1 Read from Databases

```
> library(RODBC)
> Connection <- odbcConnect(dsn="servername",uid="userid",pwd="*****")
> Query <- "SELECT * FROM lib.table WHERE ..."
> # or read query from file
> # Query <- readChar("data/myQuery.sql", nchars=99999)
> myData <- sqlQuery(Connection, Query, errors=TRUE)
> odbcCloseAll()
```

There are also sqlSave and sqlUpdate for writing or updating a table in an ODBC database.

### 2.4.2 Output to and Input from EXCEL Files

```
> library(RODBC)
> filename <- "data/dummmyData.xls"
> xlsFile <- odbcConnectExcel(filename, readOnly = FALSE)
> sqlSave(xlsFile, a, rownames = FALSE)
> b <- sqlFetch(xlsFile, "a")
> odbcCloseAll()
```

Note that there is a limit of the number of rows to write to an EXCEL file.

## Chapter 3

## **Data Exploration**

This chapter shows examples on data exploration in R. It starts with inspecting the dimensionality, structure and data of an R object, followed by basic statistics and various charts like pie charts and histograms. Exploration of multiple variables are then demonstrated, including grouped distribution, grouped boxplots, scattered plot and pairs plot. After that, examples are given on level plot, contour plot and 3D plot. It also shows how to saving charts to files with various formats.

### 3.1 Have a Look at Data

The iris data is used in this chapter for demonstration of data exploration in R. See Section 1.3.1 for details of the iris data.

Check the dimensionality

```
> dim(iris)
[1] 150
   Variable names or column names
> names(iris)
[1] "Sepal.Length" "Sepal.Width" "Petal.Length" "Petal.Width"
[5] "Species"
  Structure
> str(iris)
'data.frame':
                      150 obs. of 5 variables:
 $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
 $ Sepal.Width: num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
 $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
 $ Petal.Width : num    0.2    0.2    0.2    0.2    0.4    0.3    0.2    0.2    0.1    ...
               : Factor w/ 3 levels "setosa", "versicolor", ...: 1 1 1 1 1 1 1 1 1 1 ...
 $ Species
   Attributes
> attributes(iris)
```

#### \$names

Box plot, also known as box-and-whisker plot, shows the median, first and third quartile of a distribution (i.e., the 50%, 25% and 75% points in cumulative distribution), and outliers. The bar in the middle is the median. The box shows the interquartile range (IQR), which is the range between the 75% and 25% observation.

# **Decision Trees and Random Forest**

There are a couple of R packages on decision trees, regression trees and random forest, such as rpart, rpartOrdinal, randomForest, party, tree, marginTree and maptree.

This chapter shows how to build predictive models with packages party, rpart and random-Forest. It starts with building decision trees with package party and using the built tree for classification, followed by another way to build decision trees with package rpart. After that, it presents an example on training a random forest model with package randomForest.

## 4.1 Building Decision Trees with Package party

This section shows how to build a decision tree for iris data (see Section 1.3.1 for details of the data) with ctree in package party [Hothorn et al., 2010]. Sepal.Length, Sepal.Width, Petal.Length and Petal.Width are used to predict the Species of flowers. In the package, function ctree() builds a decision tree, and predict() makes prediction for unlabeled data.

The iris data is split below into two subsets: training (70%) and testing (30%).

```
> str(iris)
                      150 obs. of 5 variables:
'data.frame':
 $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
 $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
 $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
 $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
 $ Species
               : Factor w/ 3 levels "setosa", "versicolor", ...: 1 1 1 1 1 1 1 1 1 1 ...
> set.seed(1234)
> ind <- sample(2, nrow(iris), replace=TRUE, prob=c(0.7, 0.3))</pre>
> trainData <- iris[ind==1,]</pre>
> testData <- iris[ind==2,]</pre>
  Load package party, build a decision tree, and check the prediction.
> library(party)
> myFormula <- Species ~ Sepal.Length + Sepal.Width + Petal.Length + Petal.Width
> iris_ctree <- ctree(myFormula, data=trainData)</pre>
> # check the prediction
> table(predict(iris_ctree), trainData$Species)
             setosa versicolor virginica
  setosa
                 40
                              0
                                         0
```

3

31

After that, we can have a look at the built tree by printing the rules and plotting the tree.

#### > print(iris\_ctree)

#### Conditional inference tree with 4 terminal nodes

Response: Species

Inputs: Sepal.Length, Sepal.Width, Petal.Length, Petal.Width

Number of observations: 112

- 1) Petal.Length  $\leq$  1.9; criterion = 1, statistic = 104.643
  - 2)\* weights = 40
- 1) Petal.Length > 1.9
  - 3) Petal.Width <= 1.7; criterion = 1, statistic = 48.939
    - 4) Petal.Length <= 4.4; criterion = 0.974, statistic = 7.397
      - 5)\* weights = 21
    - 4) Petal.Length > 4.4
      - 6)\* weights = 19
  - 3) Petal.Width > 1.7
    - 7)\* weights = 32

#### > plot(iris\_ctree)

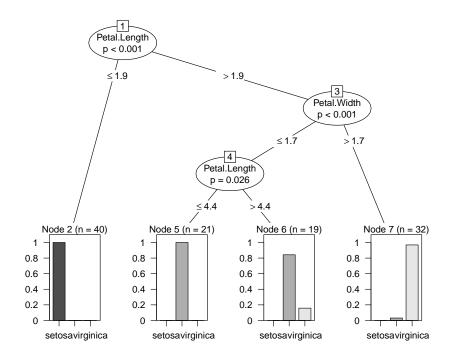

Figure 4.1: Decision Tree

> plot(iris\_ctree, type="simple")

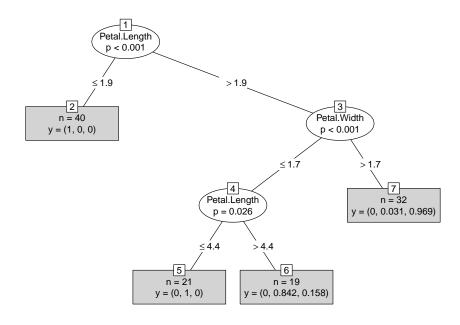

Figure 4.2: Decision Tree (Simple Style)

Test the built tree with test data.

- > # predict on test data
- > testPred <- predict(iris\_ctree, newdata = testData)
- > table(testPred, testData\$Species)

| testPred   | ${\tt setosa}$ | ${\tt versicolor}$ | virginica |
|------------|----------------|--------------------|-----------|
| setosa     | 10             | 0                  | 0         |
| versicolor | 0              | 12                 | 2         |
| virginica  | 0              | 0                  | 14        |

The current version of ctree() (i.e. version 0.9-9995) does not handle missing values well. An instance with a missing value may sometimes go to the left sub-tree and sometimes to the right. It might be because of surrogate rules.

Another issue is that, when a variable exists in training data and is fed into ctree() but does not appear in the built decision tree, the test data must also have that variable to make prediction. Otherwise, a call to predict() would fail. Moreover, if the value levels of a categorical variable in test data are different from that in train data, it would also fail to make prediction on the test data. One way to get around the above issue is, after building a decision tree, to call ctree() to build a new decision tree with data containing only those variables existing in the first tree, and to explicitly set the levels of categorical variables in test data to the levels of the corresponding variables in train data.

## 4.2 Building Decision Trees with Package rpart

Package rpart [Therneau et al., 2010] is used to build a decision tree on bodyfat data (see Section 1.3.2 for details of the data). Function rpart() is used to build a decision tree, and the tree with the minimum prediction error is select. After that, it is applied to makes prediction for unlabeled data with function predict().

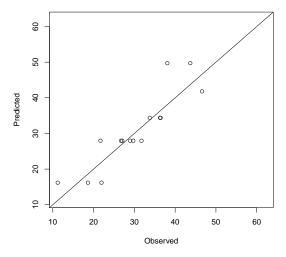

Figure 4.4: Prediction Result

## 4.3 Random Forest

Package randomForest [Liaw and Wiener, 2002] is used below to build a predictive model for iris data (see Section 1.3.1 for details of the data). There are two limitations with function randomForest(). First, it cannot handle data with missing values, and users have to impute data before feeding them into the function. Second, there is a limit of 32 to the maximum number of levels in each categorical attribute. Attributes with more than 32 levels have to be transformed first before using randomForest().

An alternative way to build a random forest is to use function cforest from package party, which is not limited to the above maximum levels.

The iris data is split below into two subsets: training (70%) and testing (30%).

```
> ind <- sample(2, nrow(iris), replace=TRUE, prob=c(0.7, 0.3))
> trainData <- iris[ind==1,]
> testData <- iris[ind==2,]</pre>
```

Load randomForest and then train a random forest.

- > library(randomForest)
- > rf <- randomForest(Species  $\tilde{\ }$  ., data=trainData, ntree=100, proximity=TRUE)
- > table(predict(rf), trainData\$Species)

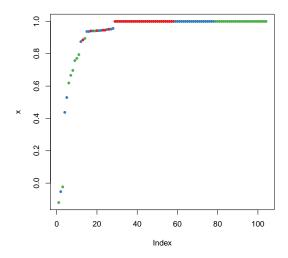

Figure 4.7: Margin of Predictions

The margin of a data point is as the proportion of votes for the correct class minus maximum proportion of votes for the other classes. Generally speaking, positive margin means correct classification.

# Chapter 5

# Regression

Regression is to build a function of *independent variables* (also known as *predictors*) to predict a *dependent variable* (also called *response*). For example, banks assess the risk of home-loan customers based on their age, income, expenses, occupation, number of dependents, total credit limit, etc.

This chapter introduces basic concepts and presents examples of various regression techniques. At first, it shows an example on building a linear regression model to predict CPI data. After that, it introduces logistic regression. The generalized linear model (GLM) is then presented, followed by a brief introduction of non-linear regression.

A collection of some helpful R functions for regression analysis is available as a reference card on R Functions for Regression Analysis  $^{1}$ .

## 5.1 Linear Regression

Linear regression is to predict response with a linear function of predictors as follows:

$$y = c_0 + c_1 x_1 + c_2 x_2 + \dots + c_k x_k,$$

where  $x_1, x_2, \dots, x_k$  are predictors and y is the response to predict.

Linear regression is demonstrated below with function 1m on the Australian CPI (Consumer Price Index) data, which are CPIs in four quarters in every year from 2008 to 2010 <sup>2</sup>.

<sup>1</sup>http://cran.r-project.org/doc/contrib/Ricci-refcard-regression.pdf

<sup>&</sup>lt;sup>2</sup>From Australian Bureau of Statistics <a href="http://www.abs.gov.au">http://www.abs.gov.au</a>

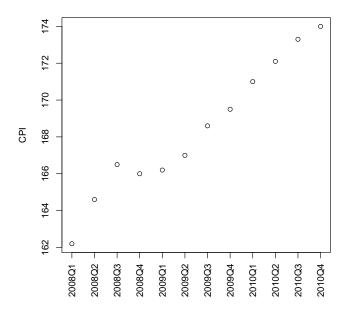

Figure 5.1: Australian CPIs in Year 2008 to 2010

We check the correlation between CPI and the other variables, year and quarter.

```
> cor(year,cpi)
```

## [1] 0.9096316

> cor(quarter,cpi)

#### [1] 0.3738028

Then a linear regression model is built on the above data, using year and quarter as predictors and CPI as response.

With the above linear model, CPI is calculated as

$$cpi = c_0 + c_1 * year + c_2 * quarter,$$

where  $c_0$ ,  $c_1$  and  $c_2$  are coefficients from model fit. Therefore, the CPIs in 2011 can be get as follows. A simpler way for this is using function predict, which will be demonstrated at the end of this subsection.

> cpi2011 <- fit\$coefficients[[1]] + fit\$coefficients[[2]]\*2011 + fit\$coefficients[[3]]\*(1:4)

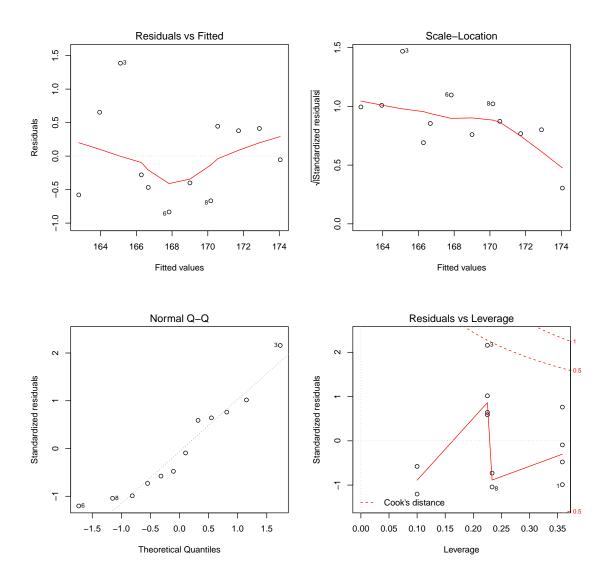

Figure 5.2: Prediction with Linear Regression Model - 1

With the model, the CPIs in year 2011 can be predicted as follows, and the predicted values are shown as red triangles in Figure 5.3.

```
> data2011 <- data.frame(year=2011, quarter=1:4)
> cpi2011 <- predict(fit, newdata=data2011)
> style <- c(rep(1,12), rep(2,4))
> plot(c(cpi, cpi2011), xaxt="n", ylab="CPI", xlab="", pch=style, col=style)
> axis(1, at=1:16, las=3,
+ labels=c(paste(year,quarter,sep="Q"), "2011Q1", "2011Q2", "2011Q3", "2011Q4"))
```

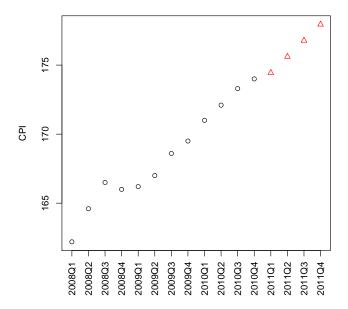

Figure 5.3: Prediction of CPIs in 2011 with Linear Regression Model

## 5.2 Logistic Regression

Logistic regression is used to predict the probability of occurrence of an event by fitting data to a logistic curve. A logistic regression model is built as the following equation:

$$logit(y) = c_0 + c_1x_1 + c_2x_2 + \dots + c_kx_k,$$

where  $x_1, x_2, \dots, x_k$  are predictors, y is a response to predict, and  $logit(y) = ln(\frac{y}{1-y})$ . The above equation can also be written as

$$y = \frac{1}{1 + e^{-(c_0 + c_1 x_1 + c_2 x_2 + \dots + c_k x_k)}}.$$

Logistic regression can be built with function glm by setting family to binomial(link="logit"). Detailed introductions on logistic regression can be found at the following links.

- R Data Analysis Examples Logit Regression http://www.ats.ucla.edu/stat/r/dae/logit.htm
- Logistic Regression (with R) http://nlp.stanford.edu/~manning/courses/ling289/logistic.pdf

## 5.3 Generalized Linear Regression

The generalized linear model (GLM) generalizes linear regression by allowing the linear model to be related to the response variable via a link function and by allowing the magnitude of the variance of each measurement to be a function of its predicted value. It unifies various other statistical models, including linear regression, logistic regression and Poisson regression. Function glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

A generalized linear model is built below with glm on bodyfat data (see Section 1.3.2 for details of the data).

```
> data("bodyfat", package = "mboost")
> myFormula <- DEXfat ~ age + waistcirc + hipcirc + elbowbreadth + kneebreadth
> bodyfat.glm <- glm(myFormula, family = gaussian("log"), data = bodyfat)</pre>
> summary(bodyfat.glm)

                      0.028193
kneebreadth 0.063188
Signif. codes: 0 Ś***Š 0.001 Ś**Š 0.01 Ś*Š 0.05 Ś.Š 0.1 Ś Š 1
(Dispersion parameter for gaussian family taken to be 20.31433)
    Null deviance: 8536.0 on 70 degrees of freedom
Residual deviance: 1320.4 on 65 degrees of freedom
AIC: 423.02
Number of Fisher Scoring iterations: 5
> pred <- predict(bodyfat.glm, type = "response")</pre>
```

In the code above, type indicates the type of prediction required. The default is on the scale of the linear predictors, and the alternative "response" is on the scale of the response variable.

> plot(bodyfat\$DEXfat, pred, xlab="Observed Values", ylab="Predicted Values")

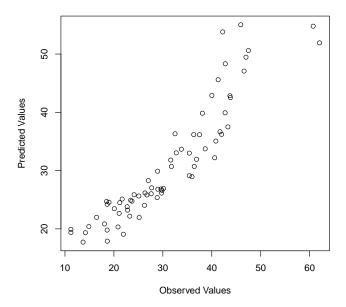

Figure 5.4: Prediction with Generalized Linear Regression Model

In the above code, if family = gaussian("identity") is used, the resulted model would be similar to linear regression. One can also make it a logistic regression by setting family to binomial("logit").

## 5.4 Non-linear Regression

While linear regression is to find the line that comes closest to data, non-linear regression is to fit a curve through data. Function nls provides nonlinear regression. More details on non-linear regression can be found at

• A Complete Guide to Nonlinear Regression http://www.curvefit.com/.

# Chapter 6

# Clustering

This chapter presents examples of various clustering techniques, including k-means clustering, hierarchical clustering and density-based clustering. The first section demonstrates how to use k-means algorithm to cluster the iris data. The second section shows an example on hierarchical clustering on the same data. The third section describes the basic idea of density-based clustering and the DBSCAN algorithm, and shows how to cluster with DBSCAN and then label new data with the clustering model.

## 6.1 k-Means Clustering

[1] 23.87947 15.15100 39.82097 (between\_SS / total\_SS = 88.4 %)

This section shows k-means clustering of iris data (see Section 1.3.1 for details of the data).

```
> iris2 <- iris
> # remove species from the data to cluster
> iris2$Species <- NULL
  Apply kmeans() to iris2, and store the clustering result in kc. The cluster number is set to
3.
> (kmeans.result <- kmeans(iris2, 3))</pre>
K-means clustering with 3 clusters of sizes 38, 50, 62
Cluster means:
 Sepal.Length Sepal.Width Petal.Length Petal.Width
    6.850000
             3.073684
                       5.742105
    5.006000
             3.428000
                       1.462000
                                 0.246000
             2.748387
    5.901613
                       4.393548
                                 1.433871
Clustering vector:
 [100] 3 1 3 1 1 1 1 3 1 1 1 1 1 1 1 3 3 1 1 1 1 3 1 3 1 3 1 1 1 3 3 1 1 1 1
[133] 1 3 1 1 1 1 3 1 1 1 3 1 1 1 3 1 1 3
Within cluster sum of squares by cluster:
```

Available components:

```
[1] "cluster" "centers" "totss" "withinss" [5] "tot.withinss" "betweenss" "size"
```

Compare the Species label with the clustering result

> table(iris\$Species, kmeans.result\$cluster)

```
1 2 3
setosa 0 50 0
versicolor 2 0 48
virginica 36 0 14
```

The above result shows that cluster "setosa" can be easily separated from the other clusters, and that clusters "versicolor" and "virginica" are to a small degree overlapped with each other.

Plot the clusters and their centers. Note that there are four dimensions in the data and that only the first two dimensions are used to draw the plot below. Some black points close to the green center (asterisk) are actually closer to the black center in the four dimensional space. Note that the results of k-means clustering may vary from run to run, due to random selection of initial cluster centers.

```
> plot(iris2[c("Sepal.Length", "Sepal.Width")], col = kmeans.result$cluster)
> points(kmeans.result$centers[,c("Sepal.Length", "Sepal.Width")], col = 1:3,
+ pch = 8, cex=2)
```

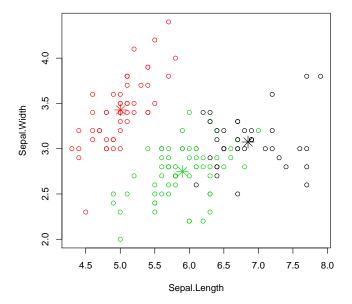

Figure 6.1: Results of k-Means Clustering

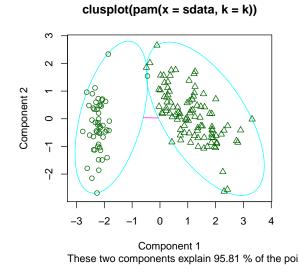

## 6.2 k-Medoids Clustering

This sections shows k-medoids clustering with functions pam() and pamk(). The k-medoids clustering is very similar to k-means, and the major difference between them is that: while a cluster

is represented with its center in the k-means algorithm, it is represented with the object closest to the center of the cluster in the k-medoids clustering. The k-medoids clustering is more robust than k-means in presence of outliers. PAM (Partitioning Around Medoids) is a classic algorithm for k-medoids clustering. While the PAM algorithm is inefficient for clustering large data, the CLARA algorithm is an enhanced technique of PAM by drawing multiple samples of data, appling PAM on each sample and then returning the best clustering. It performs better than PAM on larger data. Functions pam() and clara() in package cluster [Maechler et al., 2012] are respectively implementations of PAM and CLARA in R. For both algoritms, a user has to specify k, the number of clusters to find. As an enhanced version of pam(), function pamk() in package fpc [Hennig, 2010] does not require a user to choose k. Instead, it calls the function pam() or clara() to perform a partitioning around medoids clustering with the number of clusters estimated by optimum average silhouette width.

With the code below, we demonstrate how to find clusters with pam() and pamk().

```
> library(fpc)
> pamk.result <- pamk(iris2)
> # number of clusters
> pamk.result$nc
[1] 2
> # check clustering against real species
> table(pamk.result$pamobject$clustering, iris$Species)
    setosa versicolor virginica
 1
        50
                    1
 2
         0
                   49
                             50
> layout(matrix(c(1,2),1,2)) # 2 graphs per page
> plot(pamk.result$pamobject)
> layout(matrix(1)) # change back to one graph per page
```

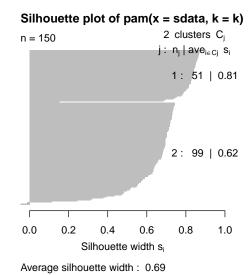

Figure 6.2: Clustering with the k-medoids Algorithm - I

In the above example, pamk() produces two clusters: one is "setosa", and the other is a mixture of "versicolor" and "virginica". In Figure 6.2, the left chart is a 2-dimensional "clusplot" (clustering

plot) of the two clusters and the lines show the distance between clusters. The right one shows their silhouettes. In the silhouette, a large  $s_i$  (almost 1) suggests that the corresponding observations are very well clustered, a small  $s_i$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s_i$  are probably placed in the wrong cluster. Since the average  $S_i$  are respectively 0.81 and 0.62 in the above silhouette, the identified two clusters are well clustered.

Next, we try pam() with k = 3.

```
> pam.result <- pam(iris2, 3)
> table(pam.result$clustering, iris$Species)
```

|   | setosa | versicolor | virginica |
|---|--------|------------|-----------|
| 1 | 50     | 0          | 0         |
| 2 | 0      | 48         | 14        |
| 3 | 0      | 2          | 36        |

- > layout(matrix(c(1,2),1,2)) # 2 graphs per page
- > plot(pam.result)
- > layout(matrix(1)) # change back to one graph per page

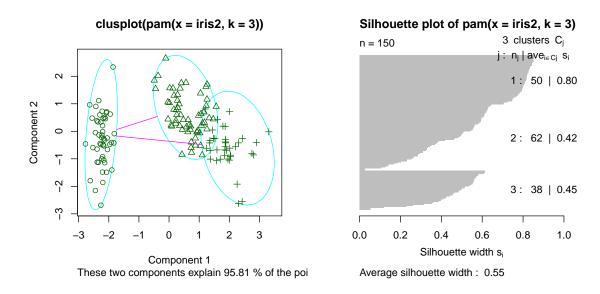

Figure 6.3: Clustering with the k-medoids Algorithm - II

With the above result produced with pam(), there are three clusters: 1) cluster 1 is species "setosa" and is well separated from the other two; 2) cluster 2 is mainly composed of "versicolor", plus some cases from "virginica"; and 3) the majority of cluster 3 are "virginica", with two cases from "versicolor".

It's hard to say which one is better out of the above two clusterings produced respectively with pamk() and pam(). It depends on the target problem and domain knowledge and experience. In this example, the result of pam() is better, because it identifies three clusters, corresponding to three species. Therefore, the heuristic way to identify the number of clusters in pamk() does not necessarily give the best result. Note that we cheat by setting k=3 when using pam(), which is already known to us as the number of species.

## 6.3 Hierarchical Clustering

This page demonstrates a hierarchical clustering with hclust() on iris data (see Section 1.3.1 for details of the data).

Draw a sample of 40 records from iris data, and remove variable Species

```
> idx <- sample(1:dim(iris)[1], 40)
> irisSample <- iris[idx,]
> irisSample$Species <- NULL

    Hierarchical clustering
> hc <- hclust(dist(irisSample), method="ave")</pre>
```

> plot(hc, hang = -1, labels=iris\$Species[idx])

# 

Figure 6.4: Cluster Dendrogram

hclust (\*, "average")

Similar to the above clustering of k-means, Figure 6.4 also shows that cluster "setosa" can be easily separated from the other two clusters, and that clusters "versicolor" and "virginica" are to a small degree overlapped with each other.

## 6.4 Density-based Clustering

DBSCAN from package fpc [Hennig, 2010] provides a density-based clustering for numeric data [Ester et al., 1996]. The idea of density-based clustering is to group objects into one cluster if they are connected to one another by densely populated area. There are two key parameters in DBSCAN:

- eps: Reachability Distance, which defines the size of neighborhood;
- MinPts: Reachability minimum no. of points.

If the number of points in the neighborhood of point  $\alpha$  is no less than MinPts, then  $\alpha$  is a *dense point*. All the points in its neighborhood are *density-reachable* from  $\alpha$  and are put into the same cluster as  $\alpha$ .

The strengths of density-based clustering are that it can discover clusters with various shapes and sizes and is insensitive to noise. As a comparison, k-means tends to find clusters with sphere shape and with similar sizes.

- > library(fpc)
- > iris2 <- iris[-5] # remove class tags</pre>
- > ds <- dbscan(iris2, eps=0.42, MinPts=5)</pre>
- > # compare clusters with original class labels
- > table(ds\$cluster, iris\$Species)

|   | ${\tt setosa}$ | ${\tt versicolor}$ | virginica |
|---|----------------|--------------------|-----------|
| 0 | 2              | 10                 | 17        |
| 1 | 48             | 0                  | 0         |
| 2 | 0              | 37                 | 0         |
| 3 | 0              | 3                  | 33        |

In the above table, "1" to "3" in the first column are three discovered clusters, while "0" stands for noises or outliers, i.e., objects that are not assigned to any clusters. The noises are shown as black circles in figures below.

#### > plot(ds, iris2)

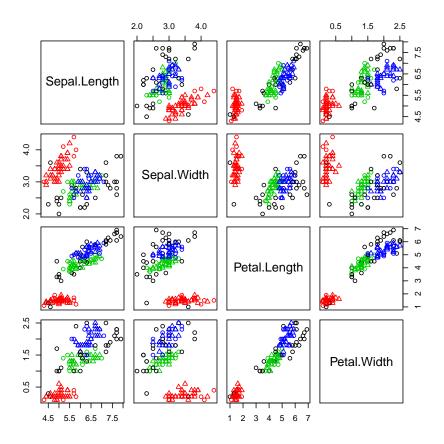

Figure 6.5: Density-based Clustering - I

## > plot(ds, iris2[c(1,4)])

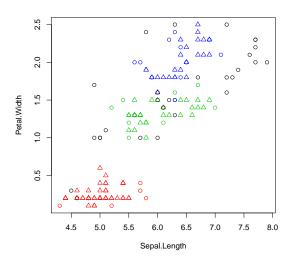

Figure 6.6: Density-based Clustering - II

Another way to show the clusters. Note that the data are projected to distinguish classes.

## > plotcluster(iris2, ds\$cluster)

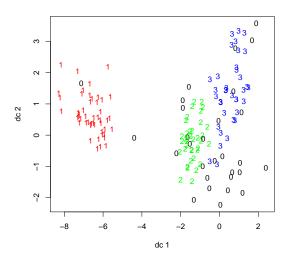

Figure 6.7: Density-based Clustering - III

## Label new data

The clustering model can then be used to label new data, based on the similarity between a new object and the clusters. The following example draws a sample of 10 objects from iris and adds small noise to them to make a new dataset for labeling.

```
> # create a new dataset for labeling
> set.seed(435)
> idx <- sample(1:nrow(iris), 10)</pre>
> newData <- iris[idx,-5]</pre>
> newData <- newData + matrix(runif(10*4, min=0, max=0.2), nrow=10, ncol=4)
> # label new data
> myPred <- predict(ds, iris2, newData)
> # check the labels assigned to new data
> plot(iris2[c(1,4)], col=1+ds$cluster)
> points(newData[c(1,4)], pch="*", col=1+myPred, cex=3)
> # check cluster labels
> table(myPred, iris$Species[idx])
myPred setosa versicolor virginica
     0
                        0
            0
            3
                        0
     1
                                  0
     2
                        3
                                  0
            0
                        1
                                  2
```

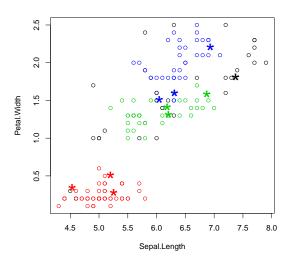

Figure 6.8: Prediction with Clustering Model

As we can see from the above result, in the 10 new unlabeled data, 8(=3+3+2) are assigned with correct class labels. The new data are shown as asterisk("\*") in the above figure and the colors stand for cluster labels.

## 6.5 Fuzzy Clustering

This section is not available yet in this version.

## 6.6 Subspace Clustering

This section is not available yet in this version.

# Chapter 7

# **Outlier Detection**

This chapter presents examples of outlier detection with R. At first, it demonstrates univariate outlier detection. After that, an example of outlier detection with LOF is given, followed by examples on outerlier detection with clustering. At last, it presents an example of outlier detection from time series data.

## 7.1 Univariate Outlier Detection

This section shows an example of univariate outlier detection, and demonstrates how to apply it to multivariate data. In the example, univariate outlier detection is done with function boxplot.stats(), which returns the statistics for producing box plots. In the result returned by the above function, one component is out, which gives a list of outliers. More specifically, it lists data points lying beyond the extremes of the whiskers. An argument of coef can be used to control how far the whiskers extend out from the box of a boxplot. More details on that can be obtained by running ?boxplot.stats in R.

```
> set.seed(3147)
> x <- rnorm(100)
> summary(x)

Min. 1st Qu. Median Mean 3rd Qu. Max.
-3.3150 -0.4837  0.1867  0.1098  0.7120  2.6860
> # outliers
> boxplot.stats(x)$out

[1] -3.315391  2.685922 -3.055717  2.571203
> boxplot(x)
```

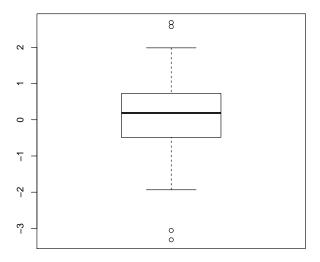

Figure 7.1: Univariate Outlier Detection with Boxplot

The above univariate outlier detection can be used to find outliers in multivariate data in a simple ensemble way. In the example below, we first generate a dataframe  $\mathtt{df}$ , which has two columns,  $\mathtt{x}$  and  $\mathtt{y}$ . After that, outliers are detected separately from  $\mathtt{x}$  and  $\mathtt{y}$ . We then take outliers as those data which are outliers for both columns. In Figure 7.2, outliers are labelled with "+" in red.

```
> attach(df)
> # find the index of outliers from x
> (a <- which(x %in% boxplot.stats(x)$out))

[1] 1 33 64 74

> # find the index of outliers from y
> (b <- which(y %in% boxplot.stats(y)$out))

[1] 24 25 49 64 74

> detach(df)

> # outliers in both x and y
> (outlier.list1 <- intersect(a,b))

[1] 64 74

> plot(df)
> points(df[outlier.list1,], col="red", pch="+", cex=2)
```

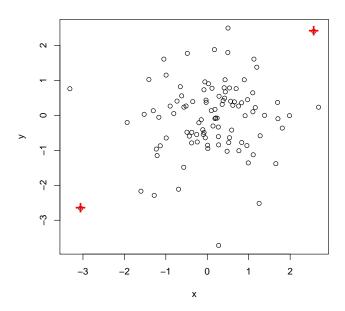

Figure 7.2: Outlier Detection - I

Similarly, we can also take outliers as those data which are outliers in either x or y. In Figure 7.3, outliers are labelled with "x" in blue.

```
> # outliers in either x or y
> (outlier.list2 <- union(a,b))

[1] 1 33 64 74 24 25 49

> plot(df)
> points(df[outlier.list2,], col="blue", pch="x", cex=1.5)
```

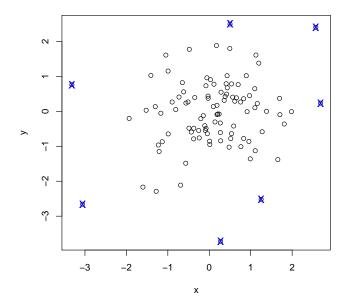

Figure 7.3: Outlier Detection - II

When there are three or more variables in an application, a final list of outliers might be produced with majority voting of outliers detected from individual variables. Domain knowledge should be involved when choosing the optimal way to ensemble in real-world applications.

## 7.2 Outlier Detection with LOF

LOF (Local Outlier Factor) is an algorithm for identifying density-based local outliers [Breunig et al., 2000]. With LOF, the local density of a point is compared with that of its neighbors. If the former is signaficantly lower than the latter (with an LOF value greater than one), the point is in a sparser region than its neighbors, which suggests it be an outlier. A short-coming of LOF is that it works on numeric data only.

Function lofactor() calculates local outlier factors using the LOF algorithm, and it is available in packages DMwR [Torgo, 2010] and dprep. An example of outlier detection with LOF is given below, where k is the number of neighbours used in the calculation of the local outlier factors.

- > library(DMwR)
- > # remove "Species", which is a categorical column
- > iris2 <- iris[,1:4]</pre>
- > outlier.scores <- lofactor(iris2, k=5)</pre>
- > plot(density(outlier.scores))

#### density.default(x = outlier.scores)

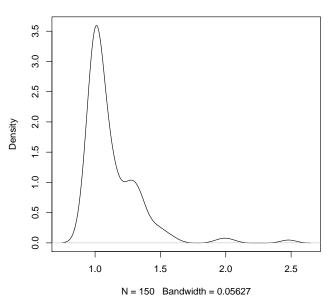

Figure 7.4: Density of outlier factors

- > # pick top 5 as outliers
- > outliers <- order(outlier.scores, decreasing=T)[1:5]</pre>
- > # who are outliers
- > print(outliers)

## [1] 42 107 23 110 63

> print(iris2[outliers,])

|     | Sepal.Length | Sepal.Width | Petal.Length | Petal.Width |
|-----|--------------|-------------|--------------|-------------|
| 42  | 4.5          | 2.3         | 1.3          | 0.3         |
| 107 | 4.9          | 2.5         | 4.5          | 1.7         |
| 23  | 4.6          | 3.6         | 1.0          | 0.2         |
| 110 | 7.2          | 3.6         | 6.1          | 2.5         |
| 63  | 6.0          | 2.2         | 4.0          | 1.0         |

Next, we show outliers with a biplot of the first two principal components.

```
> n <- nrow(iris2)
> labels <- 1:n
> labels[-outliers] <- "."
> biplot(prcomp(iris2), cex=.8, xlabs=labels)
```

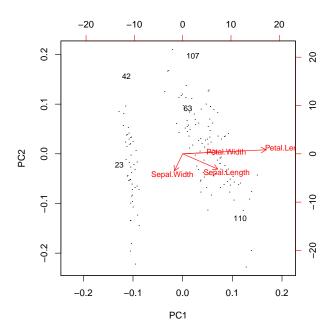

Figure 7.5: Outliers

In the above code, prcomp() performs a principal component analysis, and biplot() plots the data with its first two principal components. In Figure 7.5, the x- and y-axis are respectively the first and second principal components, the arrows show the original columns (variables), and the five outliers are labeled with their row numbers.

We can also show outliers with a pairs plot as below, where outliers are labeled with "+" in red.

```
> pch <- rep(".", n)
> pch[outliers] <- "+"
> col <- rep("black", n)
> col[outliers] <- "red"
> pairs(iris2, pch=pch, col=col)
```

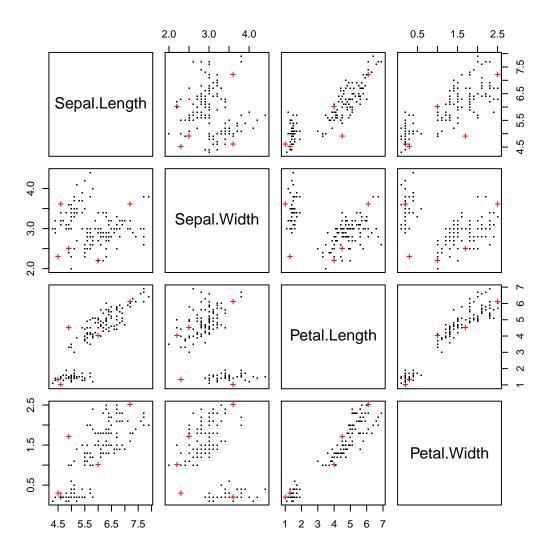

Figure 7.6: Outliers

Package Rlof [Hu et al., 2011] provides function lof(), a parallel implementation of the LOF algorithm. Its usage is similar to the above lofactor(), but lof() has two additional features of supporting multiple values of k and several choices of distance metrics. Below is an example of lof(). After computing outlier scores, outliers can be detected by selecting the top ones.

```
> library(Rlof)
> outlier.scores <- lof(iris2, k=5)
> # try with different number of neighbours (k = 5,6,7,8,9 and 10)
> outlier.scores <- lof(iris2, k=c(5:10))</pre>
```

## 7.3 Outlier Detection by Clustering

Another way to detecte outliers is clustering. By grouping data into clusters, those data not assigned to any clusters are taken as outliers. For example, with density-based clustering such as DBSCAN [Ester et al., 1996], objects are grouped into one cluster if they are connected to one another by densely populated area. Therefore, objects not assigned to any clusters are isolated from other objects and are taken as outliers. An example of DBSCAN be found in Section 6.4: Density-based Clustering.

We can also detect outliers with the k-means algorithm. With k-means, the data are partitioned into k groups by assigning them to the closest cluster centers. After that, we can calculate the distance (or dissimilarity) between each object and its cluster center, and pick those with largest distances as outliers. An example of outlier detection with k-means from the iris data (see Section 1.3.1 for details of the data) is given below.

```
> # remove species from the data to cluster
> iris2 <- iris[,1:4]</pre>
> kmeans.result <- kmeans(iris2, centers=3)</pre>
> # cluster centers
> kmeans.result$centers
 Sepal.Length Sepal.Width Petal.Length Petal.Width
1
    5.006000
             3.428000
                        1.462000
                                 0.246000

+ pch=8, cex=1)
> # plot outliers
> points(iris2[outliers, c("Sepal.Length", "Sepal.Width")], pch="+", col=4)
```

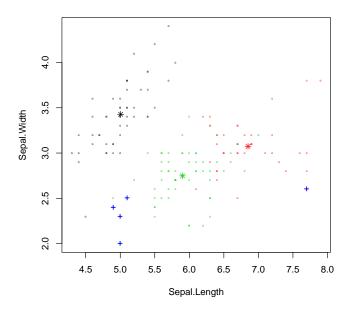

Figure 7.7: Outliers with k-Means Clustering

In the above figure, cluster centers are labeled with asterisks and outliers with "+".

## 7.4 Outlier Detection from Time Series Data

This section presents an example of outlier detection from time series data. In the example, the time series data are first decomposed with robust regression using function stl() and then outliers are identified. An introduction of STL (Seasonal-trend decomposition based on Loess) [Cleveland et al., 1990] is available at http://cs.wellesley.edu/~cs315/Papers/stl%20statistical%20model.pdf. More examples of time series decomposition can be found in Section 8.2.

```
> # use robust fitting
> f <- stl(AirPassengers, "periodic", robust=TRUE)
> (outliers <- which(f$weights<1e-8))

[1] 79 91 92 102 103 104 114 115 116 126 127 128 138 139 140

> # set layout
> op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 1))
> plot(f, set.pars=NULL)
> sts <- f$time.series
> # plot outliers
> points(time(sts)[outliers], 0.8*sts[,"remainder"][outliers], pch="x", col="red")
> par(op) # reset layout
```

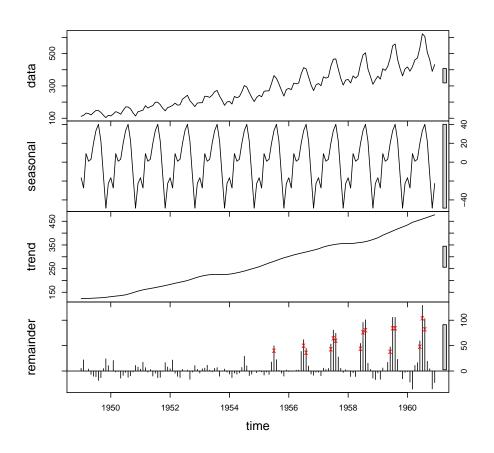

Figure 7.8: Outliers in Time Series Data

In above figure, outliers are labeled with "x" in red.

#### 7.5 Discussions

The LOF algorithm is good at detecting local outliers, but it works on numeric data only. A fast and scalable outlier detection strategy for categorical data is the Attribute Value Frequency (AVF) algorithm [Koufakou et al., 2007].

Package Rlof uses the multicore package, which does not work under Mac OS X.

7.5. DISCUSSIONS 63

Some other R packages for outlier detection are:

- Package extremevalues [van der Loo, 2010]: univariate outlier detection;
- $\bullet$  Package mvoutlier [Filzmoser and Gschwandtner, 2012]: multivariate outlier detection based on robust methods; and

• Package outliers [Komsta, 2011]: tests for outliers.

## Chapter 8

# Time Series Analysis and Mining

This chapter presents examples on time series decomposition, forecast, clustering and classification. The first section introduces briefly time series data in R. The second section shows an example on decomposing time series into trend, seasonal and random components. The third section presents how to build an autoregressive integrated moving average (ARIMA) model in R and use it to predict future values. The fourth section introduces Dynamic Time Warping (DTW) and hierarchical clustering of a time series data with Euclidean distance and with DTW distance. The fifth section shows three examples on time series classification: one with original data, the other with DWT (Discrete Wavelet Transform) transformed data, and another with k-NN classification. The chapter ends with discussions and further readings.

#### 8.1 Time Series Data in R

Class ts represents data which has been sampled at equispaced points in time. A frequency of 7 indicates that a time series is composed of weekly data, and 12 and 4 are used for respectively a monthly series and a quarterly series. An example below shows the construction of a time series with 30 values (1 to 30). Frequency=12 and start=c(2011,3) suggest that it is a monthly series starting from March 2011.

```
> a <- ts(1:30, frequency=12, start=c(2011,3))</pre>
> print(a)
     Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec
2011
                        3
                            4
                                 5
                                     6
                                              8
          12
              13
                   14
                       15
                           16
                               17
                                    18
                                        19
                                            20
                                                 21

```

## 8.2 Time Series Decomposition

Time Series Decomposition is to decompose a time series into trend, seasonal, cyclical and irregular components. The trend component stands for long term trend, the seasonal component is seasonal variation, the cyclical component is repeated but non-periodic fluctuations, and the residuals are irregular component.

A time series of AirPassengers is used below as an example to demonstrate time series decomposition. It is composed of monthly totals of Box & Jenkins international airline passengers from 1949 to 1960. It has 144(=12\*12) values.

#### > plot(AirPassengers)

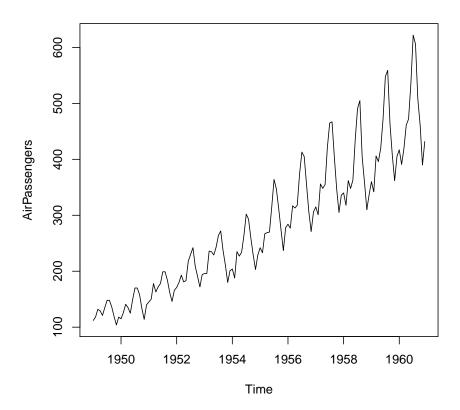

Figure 8.1: A Time Series of AirPassengers

Function decompose is called to AirPassengers to break it into various components.

```
> # decompose time series
> apts <- ts(AirPassengers, frequency = 12)
> f <- decompose(apts)
> # seasonal figures
> f$figure

[1] -24.748737 -36.188131  -2.241162  -8.036616  -4.506313  35.402778
[7] 63.830808 62.823232  16.520202 -20.642677 -53.593434 -28.619949
> plot(f$figure, type="b", xaxt="n", xlab="")
> # get names of 12 months in English words
> monthNames <- months(ISOdate(2011,1:12,1))
> # label x-axis with month names
> # las is set to 2 for vertical label orientation
> axis(1, at=1:12, labels=monthNames, las=2)
```

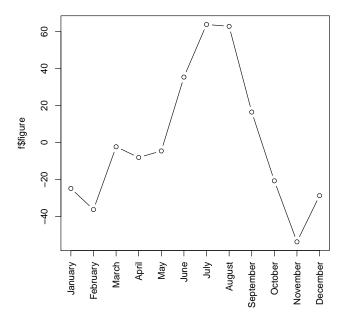

Figure 8.2: Seasonal Component

> plot(f)

#### Decomposition of additive time series

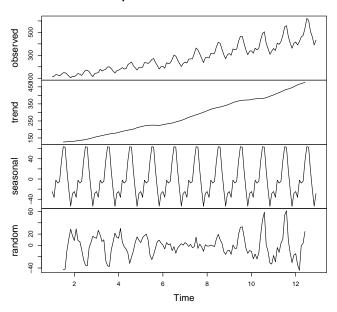

Figure 8.3: Time Series Decomposition

The first chart is the original time series. The second is trend in the data, the third shows seasonal factors, and the last chart is the remaining components after removing trend and seasonal factors. Some other functions for time series decomposition are st1() in package stats [R Development Core Team, 2012], decomp() in package timsac [of Statistical Mathematics, 2012], and tsr() in package ast.

## 8.3 Time Series Forecasting

Time series forecasting is to forecast future events based on known past data. One example is to predict the opening price of a stock based on its past performance. Some popular models are autoregressive moving average (ARMA) and autoregressive integrated moving average (ARIMA)

Here is an example to fit an ARIMA model to a univariate time series and then use it for forecasting.

```
> fit <- arima(AirPassengers, order=c(1,0,0), list(order=c(2,1,0), period=12))
> fore <- predict(fit, n.ahead=24)
> # error bounds at 95% confidence level
> U <- fore$pred + 2*fore$se
> L <- fore$pred - 2*fore$se
> ts.plot(AirPassengers, fore$pred, U, L, col=c(1,2,4,4), lty = c(1,1,2,2))
> legend("topleft", c("Actual", "Forecast", "Error Bounds (95% Confidence)"),
+ col=c(1,2,4), lty=c(1,1,2))
```

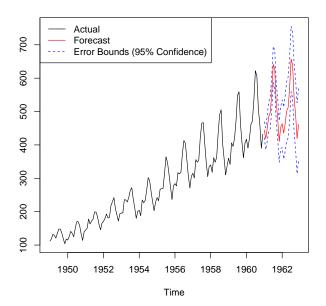

Figure 8.4: Time Series Forecast

The red solid line shows the forecasted values, and the blue dotted lines are error bounds at a confidence level of 95%.

## 8.4 Time Series Clustering

Time series clustering is to partition time series data into groups based on similarity or distance, so that time series in the same cluster are similar.

Measure of distance/dissimilarity: Euclidean distance, Manhattan distance, Maximum norm, Hamming distance, the angle between two vectors (inner product), Dynamic Time Warping (DTW) distance, etc.

### 8.4.1 Dynamic Time Warping

Dynamic Time Warping (DTW) [Keogh and Pazzani, 2001] finds optimal alignment between two time series. Package dtw [Giorgino, 2009] is used in the example below. In this package, function dtw(x, y, ...) computes dynamic time warp and finds optimal alignment between two time series x and y, and dtwDist(mx, my=mx, ...) or dist(mx, my=mx, method="DTW", ...) calculates the distances between time series mx and my.

#### > library(dtw)

Loaded dtw v1.14-3. See ?dtw for help, citation("dtw") for usage conditions.

```
> idx <- seq(0, 2*pi, len=100)
> a <- sin(idx) + runif(100)/10
> b <- cos(idx)
> align <- dtw(a, b, step=asymmetricP1, keep=T)
> dtwPlotTwoWay(align)
```

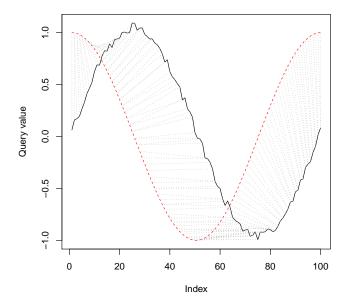

Figure 8.5: Alignment with Dynamic Time Warping

#### 8.4.2 Synthetic Control Chart Time Series Data

Synthetic Control Chart Time Series <sup>1</sup> The dataset contains 600 examples of control charts synthetically generated by the process in Alcock and Manolopoulos (1999). Each control chart is a time series with 60 values. There are six classes:

- 1-100 Normal
- 101-200 Cyclic
- 201-300 Increasing trend
- 301-400 Decreasing trend
- $\bullet$  401-500 Upward shift
- $\bullet$  501-600 Downward shift

Firstly, the data is read into R with read.table(). Parameter sep is set to "" (no space between double quotation marks), which is used when the separator is white space, i.e., one or more spaces, tabs, newlines or carriage returns.

 $<sup>^{1} \</sup>verb|http://kdd.ics.uci.edu/databases/synthetic_control/synthetic_control.html|$ 

```
> sc <- read.table("data/synthetic_control.data", header=F, sep="")
> # show one sample from each class
> idx <- c(1,101,201,301,401,501)
> sample1 <- t(sc[idx,])
> plot.ts(sample1, main="")
```

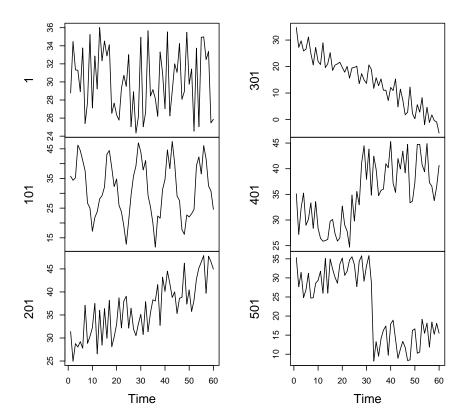

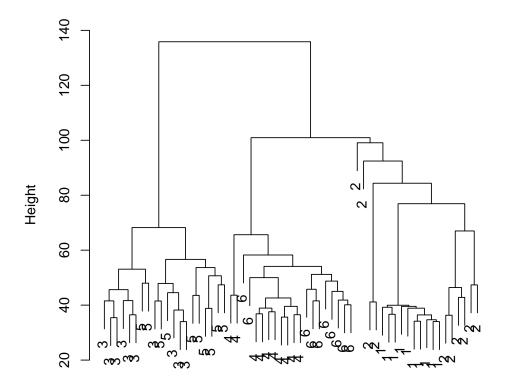

Figure 8.6: Six Classes in Synthetic Control Chart Time Series

## 8.4.3 Hierarchical Clustering with Euclidean Distance

n cases were randomly sampled from each class.

```
> n <- 10
> s <- sample(1:100, n)
> idx <- c(s, 100+s, 200+s, 300+s, 400+s, 500+s)
> sample2 <- sc[idx,]
> observedLabels <- c(rep(1,n), rep(2,n), rep(3,n), rep(4,n), rep(5,n), rep(6,n))
> # hierarchical clustering with Euclidean distance
> hc <- hclust(dist(sample2), method="ave")
> plot(hc, labels=observedLabels, main="")
```

dist(sample2)
hclust (\*, "average")

Figure 8.7: Hierarchical Clustering with Euclidean Distance

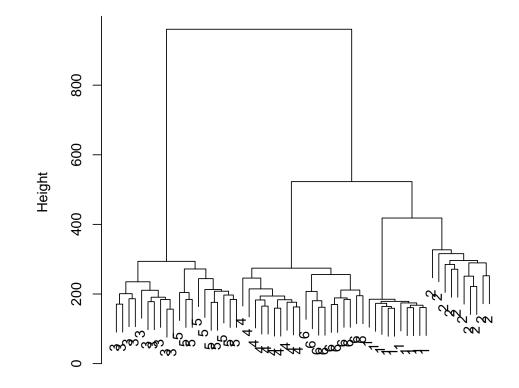

cut tree to get 8 clusters

```
> memb <- cutree(hc, k=8)
> table(observedLabels, memb)
```

```
memb
observedLabels 1 2 3 4 5 6 7 8
1 10 0 0 0 0 0 0 0 0
2 0 6 1 2 1 0 0 0
3 0 0 0 0 0 6 4 0
4 0 0 0 0 0 0 0 0 0 10
```

distMatrix
hclust (\*, "average")

Figure 8.8: Hierarchical Clustering with DTW Distance

#### 8.5 Time Series Classification

Time series classification is to build a classification model based on labeled time series and then use the model to predict the label of unlabeled time series.

Some techniques for feature extraction are Singular Value Decomposition (SVD), Discrete Fourier Transform (DFT), Discrete Wavelet Transform (DWT), Piecewise Aggregate Approximation (PAA), Perpetually Important Points (PIP), Piecewise Linear Representation, and Symbolic Representation.

## 8.5.1 Classification with Original Data

We use ctree() from package party [Hothorn et al., 2010] to demonstrate classification of time series with original data. The class labels are changed into categorical values before feeding the data into ctree, so that we won't get class labels as a real number like 1.35.

```
> classId <- c(rep("1",100), rep("2",100), rep("3",100),</pre>
                rep("4",100), rep("5",100), rep("6",100))
> newSc <- data.frame(cbind(classId, sc))</pre>
> library(party)
> ct <- ctree(classId ~ ., data=newSc,
               controls = ctree_control(minsplit=30, minbucket=10, maxdepth=5))
> pClassId <- predict(ct)</pre>
> table(classId, pClassId)
       pClassId
classId
               2
                   3
                                6
           1
                            5
      1
         97
               0
                   0
                        0
                            0
                                3
      2
          1
              93
                            0
      3
          0
               0
                  96
                        0
                            4
          0
                            0
      4
               0

#### 8.5.2 Classification with Extracted Features

DWT (Discrete Wavelet Transform) [Burrus et al., 1998]

Wavelet transform provides a multi-resolution representation using wavelets. An example of Haar Wavelet Transform, the simplest DWT, is available at http://dmr.ath.cx/gfx/haar/. DFT (Discrete Fourier Transform) is another popular feature extraction technique [Agrawal et al., 1993].

An example on extracting DWT (with Haar filter) coefficients is shown below. Package wavelets [Aldrich, 2010] is used for discrete wavelet transform. In the package, function dwt(X, filter, n.levels, ...) computes the discrete wavelet transform coefficients, where X is a univariate or multi-variate time series, filter indicates which wavelet filter to use, and n.levels specifies the level of decomposition. It returns an object of class dwt, whose slot W contains wavelet coefficients

and V contains scaling coefficients. The original time series can be reconstructed via an inverse discrete wavelet transform with function idwt() in the same package.

```
> library(wavelets)
> wtData <- NULL
> for (i in 1:nrow(sc)) {
    a <- t(sc[i,])
    wt <- dwt(a, filter="haar", boundary="periodic")</pre>
    wtData <- rbind(wtData,</pre>
    unlist(c(wt@W, wt@V[[wt@level]])))
+ }
> wtData <- as.data.frame(wtData)</pre>
> wtSc <- data.frame(cbind(classId, wtData))</pre>
  Decision Tree with DWT
> ct <- ctree(classId ~ ., data=wtSc,
              controls = ctree_control(minsplit=30, minbucket=10, maxdepth=5))
> pClassId <- predict(ct)</pre>
> table(classId, pClassId)
       pClassId
classId 1 2
               3
                  4
      1 97
            3
                  0 0
        1 99
               0
                  0
                    0
               0 63
                     0 37
      5
            0 16
                 0 84
         0
        0 0 0 1 0 99
> (sum(classId==pClassId)) / nrow(wtSc)
```

#### [1] 0.8716667

> plot(ct, ip\_args=list(pval=FALSE), ep\_args=list(digits=0))

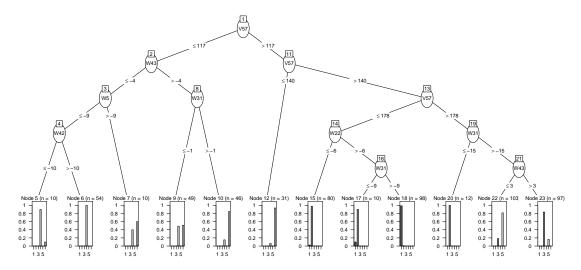

Figure 8.10: Decision Tree with DWT

#### 8.5.3 k-NN Classification

k-NN Classification find the k nearest neighbors of a new instance; label it by majority voting; needs an ecient indexing structure for large datasets

```
> k <- 20
> newTS <- sc[501,] + runif(100)*15
> distances <- dist(newTS, sc, method="DTW")
> s <- sort(as.vector(distances), index.return=TRUE)
> # class IDs of k nearest neighbors
> table(classId[s$ix[1:k]])
4 6
3 17
```

For the 20 nearest neighbors of the new time series, three of them are of class 4, and 17 are of class 6. With majority voting, that is, taking the more frequent label as winner, the label of the new time series is set to class 6.

#### 8.6 Discussion

There are many R functions and packages available for time series decomposition and forecasting. However, there are no R functions or packages specially time series classification and clustering. There are a lot of research publications on techniques specially for classifying/clustering time series data, but no R implementations (as far as I know).

To do time series classification, one is suggested to extract and build features first, and then apply existing classification techniques, such as SVM, k-NN, neural networks, regression and decision trees, to the feature set.

For time series clustering, one needs to work out his/her own distance or similarity metrics, and then use existing clustering techniques, such as k-means or hierarchical clustering, to find clustering structure.

## 8.7 Further Readings

An introduction of R functions and packages for time series is available as CRAN Task View: Time Series Analysis at http://cran.r-project.org/web/views/TimeSeries.html.

R code examples for time series can be found in slides  $\mathit{Time Series Analysis}$  and  $\mathit{Mining with}$   $\mathit{R}$  at http://www.rdatamining.com/docs.

Some further readings on time series representation, similarity, clustering and classification are [Agrawal et al., 1993, Burrus et al., 1998, Chan and Fu, 1999, Chan et al., 2003, Keogh and Pazzani, 1998, Keogh et al., 2000, Keogh and Pazzani, 2000, Mörchen, 2003, Rafiei and Mendelzon, 1998, Vlachos et al., 2003, Wu et al., 2000, Zhao and Zhang, 2006].

## Chapter 9

# **Association Rules**

This chapter presents examples of association rule mining with R. It demonstrates association rules mining, pruning redundant rules and visualizing association rules.

#### 9.1 The Titantic Dataset

The Titantic dataset in the *datasets* package is a 4-dimensional table with summarized information on the fate of passengers on the Titanic according to social class, sex, age and survival. To make it suitable for association rule mining, we reconstruct the raw data, where each row represents a person.

```
> str(Titanic)
 table [1:4, 1:2, 1:2, 1:2] 0 0 35 0 0 0 17 0 118 154 ...
 - attr(*, "dimnames")=List of 4
  ..$ Class : chr [1:4] "1st" "2nd" "3rd" "Crew"
  ..$ Sex
              : chr [1:2] "Male" "Female"
  ..$ Age
              : chr [1:2] "Child" "Adult"
  ..$ Survived: chr [1:2] "No" "Yes"
> df <- as.data.frame(Titanic)</pre>
> head(df)
 Class
           Sex
                 Age Survived Freq
          Male Child
                            No
1
    1st
                                  0
    2nd
          Male Child
                                  0
                            No
3
   3rd
          Male Child
                            No
                                 35
4
   Crew
          Male Child
                            No
                                  0
5
    1st Female Child
                            No
                                  0
    2nd Female Child
> titanic.raw <- NULL
> for(i in 1:4) {
     titanic.raw <- cbind(titanic.raw, rep(as.character(df[,i]), df$Freq))</pre>
> titanic.raw <- as.data.frame(titanic.raw)
> names(titanic.raw) <- names(df)[1:4]
> dim(titanic.raw)
[1] 2201
```

```
> str(titanic.raw)
'data.frame':
                     2201 obs. of 4 variables:
           : Factor w/ 4 levels "1st", "2nd", "3rd", ...: 3 3 3 3 3 3 3 3 3 3 ...
           : Factor w/ 2 levels "Female", "Male": 2 2 2 2 2 2 2 2 2 ...
           : Factor w/ 2 levels "Adult", "Child": 2 2 2 2 2 2 2 2 2 ...
 $ Age
 $ Survived: Factor w/ 2 levels "No", "Yes": 1 1 1 1 1 1 1 1 1 1 ...
> head(titanic.raw)
  Class Sex
               Age Survived
    3rd Male Child
                          Nο
1
2
    3rd Male Child
                          No
3
    3rd Male Child
                          No
4
    3rd Male Child
                          No
    3rd Male Child
5
                          No
    3rd Male Child
                          No
> summary(titanic.raw)
 Class
                Sex
                              Age
                                        Survived
 1st :325
            Female: 470
                           Adult:2092
                                        No:1490
 2nd:285
            Male :1731
                           Child: 109
                                        Yes: 711
 3rd:706
 Crew:885
```

Now we have a dataset where each row stands for a person, and it can be used for association rule mining. The raw Titanic dataset can also be downloaded from http://www.cs.toronto.edu/~delve/data/titanic/desc.html. The data is file "Dataset.data" in the compressed archive "titanic.tar.gz". It can be read into R with the code below.

```
> # have a look at the 1st 5 lines
> readLines("data/Dataset.data", n=5)

[1] "1st adult male yes" "1st adult male yes" "1st adult male yes"

[4] "1st adult male yes" "1st adult male yes"

> # read it into R
> titanic <- read.table("data/Dataset.data", header=F)
> names(titanic) <- c("Class", "Sex", "Age", "Survived")</pre>
```

## 9.2 Association Rule Mining

A classic algorithm for association rule mining is APRIORI [Agrawal and Srikant, 1994]. It is a level-wise, breadth-first algorithm which counts transactions to find frequent itemsets and then derive association rules from frequent itemsets. An implemention of it is function apriori() in package arules. Another algorithm for association rule mining is the ECLAT algorithm [Zaki, 2000], which finds frequent itemsets with equivalence classes, depth-first search and set intersection instead of counting. It is implemented as function eclat() in the same package.

Below we demonstrate association rule mining with apriori(). With the function, the default settings are: 1) supp=0.1, which is the minimum support of rules; 2) conf=0.8, which is the minimum confidence of rules; and 3) maxlen=10, which is the maximum length of rules.

```
> library(arules)
> # find association rules with default settings
> rules <- apriori(titanic.raw)</pre>
```

```

As a common phenomenon is assocition rule mining, many rules generated above are uninteresting. Suppose that we are interested in only rules with rhs indicating survival, so we set rhs=c("Survived=No", "Survived=Yes") in appearance to make sure that only "Survived=No" and "Survived=Yes" will appear in the rhs of rules. All items can appear in the lhs, as set with default="lhs". In the above result, we can also see that the left-hand side (lhs) of the first rule is empty. To exclude such rules, we set minlen to 2 in the code below. Moreover, the details of progress are suppressed with verbose=F. After association rule mining, rules are sorted by lift to make high-lift rules appear first.

```
> # rules with rhs containing "Survived" only
> rules <- apriori(titanic.raw,
                   parameter = list(minlen=2, supp=0.005, conf=0.8),
                   appearance = list(rhs=c("Survived=No", "Survived=Yes"),
                                     default="lhs"),
                   control = list(verbose=F))
> rules.sorted <- sort(rules, by="lift")</pre>
> inspect(rules.sorted)
                                      support confidence
1 {Class=2nd,
   Age=Child} => {Survived=Yes} 0.010904134 1.0000000 3.095640
2 {Class=2nd,

11 {Class=3rd,
    Sex=Male,
               => {Survived=No} 0.175829169 0.8376623 1.237379
    Age=Adult}
12 {Class=3rd,
   Sex=Male}
               => {Survived=No} 0.191731031 0.8274510 1.222295
```

When other settings are unchanged, with a lower minumum support, more rules will be produced, and the associations between itemsets shown in the rules will be more likely to be by chance. In the above code, the minmum support is set to 0.005, so each rule is supported at least by 12 (=ceiling(0.005 \* 2201)) cases, which is acceptable for a population of 2201.

Support, confidence and lift are three common measures for selecting interesting association rules. Besides them, there are many other interestingness measures, such as chi-square, conviction, gini and leverage [Tan et al., 2002]. More than twenty measures can be calculated with function interestMeasure() in the *arules* package.

## 9.3 Removing Redundancy

From the above rules, we can see that some rules provide little or no extra information when some other rules are in the result. For example, the above rule 2 provides no extra knowledge in addition to rule 1, since rules 1 tells us that all 2nd-class children survived. Generally speaking, when a rule (such as rule 2) is a super rule of another rule (such as rule 1) and the former has the same or a lower lift, the former rule (rule 2) is considered to be redundant. Other redundant rules in the above result are rules 4, 7 & 8, compared respectively with rules 3, 6 & 5.

Below we prune redundant rules. Note that the rules have been sorted descendingly by lift.

```
> # find redundant rules
> subset.matrix <- is.subset(rules.sorted, rules.sorted)
> subset.matrix[lower.tri(subset.matrix, diag=T)] <- NA
> redundant <- colSums(subset.matrix, na.rm=T) >= 1
> which(redundant)
[1] 2 4 7 8
> # remove redundant rules
> rules.pruned <- rules.sorted[!redundant]</pre>
> inspect(rules.pruned)
 lhs
                                      support confidence
                                                             lift
1 {Class=2nd,
              => {Survived=Yes} 0.010904134 1.0000000 3.095640
   Age=Child}
2 {Class=1st,
   Sex=Female} => {Survived=Yes} 0.064061790 0.9724138 3.010243
3 {Class=2nd,
```

```
Sex=Female => {Survived=Yes} 0.042253521
                                               0.8773585 2.715986
4 {Class=Crew,
  Sex=Female > {Survived=Yes} 0.009086779
                                               0.8695652 2.691861
5 {Class=2nd,
  Sex=Male,
   Age=Adult}
               => {Survived=No}
                                 0.069968196
                                               0.9166667 1.354083
6 {Class=2nd,
  Sex=Male}
               => {Survived=No}
                                  0.069968196
                                               0.8603352 1.270871
7 {Class=3rd,
   Sex=Male,
   Age=Adult}
               => {Survived=No}
                                 0.175829169
                                               0.8376623 1.237379
8 {Class=3rd,
   Sex=Male}
               => {Survived=No}
                                 0.191731031
                                               0.8274510 1.222295
```

In the code above, function is.subset(r1, r2) checks whether r1 is a subset of r2 (i.e., whether r2 is a superset of r1). Function lower.tri() returns a logical matrix with TURE in lower triangle. From the above results, we can see that rules 2, 4, 7 & 8 (before redundancy removal) are successfully pruned.

## 9.4 Visualizing Association Rules

Next we show some ways to visualize association rules, including scatter plot, balloon plot, graph and parallel coordinates plot. More examples on visualizing association rules can be found in the vignettes of package *arulesViz* [Hahsler and Chelluboina, 2012] on CRAN at http://cran.r-project.org/web/packages/arulesViz/vignettes/arulesViz.pdf.

```
> library(arulesViz)
> plot(rules)
```

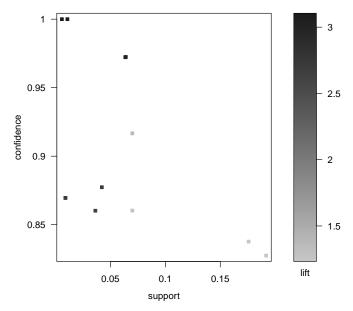

Figure 9.1: A Scatter Plot of Association Rules

> plot(rules, method="grouped")

#### Grouped matrix for 12 rules

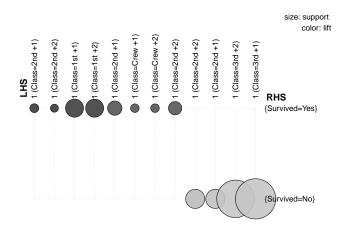

Figure 9.2: A Ballon Plot of Association Rules

## > plot(rules, method="graph")

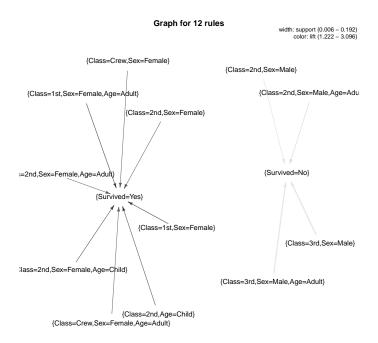

Figure 9.3: A Graph of Association Rules

> plot(rules, method="graph", control=list(type="items"))

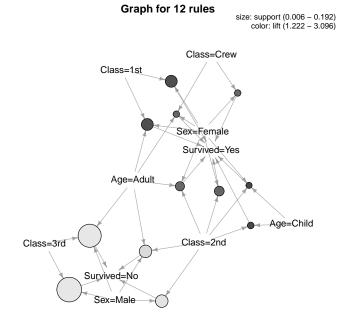

Figure 9.4: A Graph of Items

> plot(rules, method="paracoord", control=list(reorder=TRUE))

#### Parallel coordinates plot for 12 rules

## 9.5 Discussions and Further Readings

In this chapter, we have demonstrated association rule mining with package arules [Hahsler et al., 2011]. More examples on that package can be found in Hahsler et al.'s work [Hahsler et al., 2005]. Two other packages related to association rules are arulesSequences and arulesNBMiner. Package arulesSequences provides functions for mining sequential patterns [Buchta et al., 2012]. Package arulesNBMiner implements an algorithm for mining negative binomial (NB) frequent itemsets and NB-precise rules [Hahsler, 2012].

More techniques on post mining of association rules, such as selecting interesting association rules, visualization of association rules and using association rules for classification, can be found in Zhao et al's work [Zhao et al., 2009].

## Chapter 10

# Text Mining

This chapter presents examples of text mining with R. Twitter<sup>1</sup> text of @RDataMining is used as the data to analyze. It starts with extracting text from Twitter. The extracted text is then transformed to build a document-term matrix. After that, frequent words and associations are found from the matrix. A word cloud is used to present important words in documents. In the end, words and tweets are clustered to find groups of words and also groups of tweets. In this section, "tweet" and "document" will be used interchangably, so are "word" and "term".

There are three packages used in the examples: twitteR, tm and wordcloud. Package twitteR [Gentry, 2012] provides access to Twitter data, tm [Feinerer, 2012] provides functions for text mining, and wordcloud [Fellows, 2012] visualizes the result with a word cloud  $^2$ .

## 10.1 Retrieving Text from Twitter

Twitter text is used in this chapter to demonstrate text mining. Tweets are be extracted from Twitter with the code below using userTimeline() in package twitteR [Gentry, 2012].

If you have no access to Twitter, the tweets data can be downloaded as file "rdmTweets.RData" at http://www.rdatamining.com/data, and then you can skip this section and proceed directly to Section 10.2.

Package twitteR can be found at http://cran.r-project.org/bin/windows/contrib/. Package twitteR depends on package RCurl [Lang, 2012a], which is available at http://www.stats.ox.ac.uk/pub/RWin/bin/windows/contrib/2.14/. Another way to retrieve text from Twitter is using package XML [Lang, 2012b], and an example on that is given at http://heuristically.wordpress.com/2011/04/08/text-data-mining-twitter-r/.

```
> library(twitteR)
```

- > # retrieve the first 200 tweets (or all tweets if fewer than 200) from the
- > # user timeline of @rdatammining
- > rdmTweets <- userTimeline("rdatamining", n=200)</pre>
- > (nDocs <- length(rdmTweets))</pre>

#### [1] 154

Next, we have a look at the five tweets numbered 11 to 15.

#### > rdmTweets[11:15]

With the above code, each tweet is printed in one single line, which may exceed the boundary of paper. Therefore, the following code is used in this book to print the five tweets by wrapping the text to fit the width of paper. The same method is used to print tweets in other codes in this chapter.

<sup>1</sup>http://www.twitter.com

<sup>&</sup>lt;sup>2</sup>http://en.wikipedia.org/wiki/Word\_cloud

## 10.2 Transforming Text

The tweets are first converted to a data frame and then to a corpus, which is a collection of text documents. After that, the corpus can be processed with functions provided in package tm [Feinerer, 2012].

```
> # convert tweets to a data frame
> df <- do.call("rbind", lapply(rdmTweets, as.data.frame))
> dim(df)

[1] 154   10
> library(tm)
> # build a corpus, and specify the source to be character vectors
> myCorpus <- Corpus(VectorSource(df$text))</pre>
```

After that, the corpus needs a couple of transformations, including changing letters to lower case, removing punctuations, numbers and stop words. The general English stop-word list is tailored here by adding "available" and "via" and removing "r" and "big" (for big data). Hyerlinks are also removed in the example below.

```
> # convert to lower case
> myCorpus <- tm_map(myCorpus, tolower)</pre>
> # remove punctuation
> myCorpus <- tm_map(myCorpus, removePunctuation)
> # remove numbers
> myCorpus <- tm_map(myCorpus, removeNumbers)</pre>
> # remove URLs
> removeURL <- function(x) gsub("http[[:alnum:]]*", "", x)</pre>
> myCorpus <- tm_map(myCorpus, removeURL)</pre>
> # add two extra stop words: "available" and "via"
> myStopwords <- c(stopwords('english'), "available", "via")
> # remove "r" and "big" from stopwords
> idx <- which(myStopwords %in% c("r", "big"))</pre>
> myStopwords <- myStopwords[-idx]</pre>
> # remove stopwords from corpus
> myCorpus <- tm_map(myCorpus, removeWords, myStopwords)
```

In the above code, tm\_map() is an interface to apply transformations (mappings) to corpora. A list of available transformations can be obtained with getTransformations(), and the mostly used ones are as.PlainTextDocument(), removeNumbers(), removePunctuation(), removeWords(), stemDocument() and stripWhitespace(). A function removeURL() is defined to remove hypelinks. Within the function, pattern "http[[:alnum:]]\*" matches strings starting with "http" and then followed by any number of alphabetic characters and digits. Strings matching this pattern are removed with gsub(). The above pattern is specified as an regular expression, and detail about it can be found by runing ?regex in R.

## 10.3 Stemming Words

In many applications, words need to be stemmed to retrieve their radicals, so that various forms derived from a stem would be taken as the same when counting word frequency. For instance, words "update", "updated" and "updating" would all be stemmed to "updat". Word stemming can be done with the snowball stemmer, which requires packages *Snowball*, *RWeka*, *rJava* and *RWekajars*. After that, we can complete the stems to their original forms, i.e., "update" for the above example, so that the words would look normal. This can be done with function stemCompletion().

```
> # keep a copy of corpus to use later as a dictionary for stem completion
> myCorpusCopy <- myCorpus
> # stem words
> myCorpus <- tm_map(myCorpus, stemDocument)</pre>
> # inspect documents (tweets) numbered 11 to 15
> # inspect(myCorpus[11:15])
> # The code below is used for to make text fit for paper width
> for (i in 11:15) {
    cat(paste("[[", i, "]] ", sep=""))
    writeLines(strwrap(myCorpus[[i]], width=73))
[[11]] slide massiv data share distribut memoryand concurr program bigmemori
[[12]] r refer card data mine updat function packag handl big data parallel
comput
[[13]] postdoc optim cloud data mine primit inria franc
[[14]] chief scientist data intens analyt pacif northwest nation laboratori
pnnl
[[15]] top data mine
```

After that, we use stemCompletion() to complete the stems with the corpus before stemming as dictionary. With the default setting, it takes the most frequent match in dictionary as completion.

```
> # stem completion
> myCorpus <- tm_map(myCorpus, stemCompletion, dictionary=myCorpusCopy)
Then we have a look at the documents numbered 11 to 15 in the built corpus.</pre>
```

- > inspect(myCorpus[11:15])
- [[11]] slides massive data share distributed memoryand concurrent programming foreach
- [[12]] r reference card data miners updated functions package handling big data parallel computing
- [[13]] postdoctoral optimizing cloud data miners primitives inria france
- [[14]] chief scientist data intensive analytics pacific northwest national pnnl
- [[15]] top data miners

As we can see from the above results, there are something unexpected in the above stemming and completion.

- 1. In both the stemmed corpus and the completed one, "memoryand" is derived from "... memory, and ..." in the original tweet 11.
- 2. In tweet 11, word "bigmemory" is stemmed to "bigmemori", and then is removed during stem completion.
- 3. Word "mining" in tweets 12, 13 & 15 is first stemmed to "mine" and then completed to "miners".
- 4. "Laboratory" in tweet 14 is stemmed to "laboratori" and then also disappears after completion.

In the above issues, point 1 is caused by the missing of a space after the comma. It can be easily fixed by replacing comma with space before removing punction marks in Section 10.2. For points 2 & 4, we haven't figured out why it happened like that. Fortunately, the words involved in points 1, 2 & 4 are not important in @RDataMining tweets and ingoring them would not bring any harm to this demonstration of text mining.

Below we focus on point 3, where word "mining" is first stemmed to "mine" and then completed to "miners", instead of "mining", although there are many instances of "mining" in the tweets, compared to only two instances of "miners". There might be a solution for the above problem by changing the parameters and/or dictionaries for stemming and completion, but we failed to find one due to limitation of time and efforts. Instead, we chose a simple way to get around of that by replacing "miners" with "mining", since the latter has many more cases than the former in the corpus. The code for the replacement is given below.

```
> # count frequency of "mining"
> miningCases <- tm_map(myCorpusCopy, grep, pattern="\\<mining")
> sum(unlist(miningCases))

[1] 47
> # count frequency of "miners"
> minerCases <- tm_map(myCorpusCopy, grep, pattern="\\<miners")
> sum(unlist(minerCases))

[1] 2
> # replace "miners" with "mining"
> myCorpus <- tm_map(myCorpus, gsub, pattern="miners", replacement="mining")</pre>
```

In the first call of function tm\_map() in the above code, grep() is applied to every document (tweet) with argument "pattern="\\<mining". The pattern matches words starting with "mining", where "\<" matches the empty string at the beginning of a word. This ensures that text "rdatamining" would not contribute to the above counting of "mining".

## 10.4 Building a Term-Document Matrix

A term-document matrix represents the relationship between terms and documents, where each row stands for a term and each column for a document, and an entry is the number of occurrences of the term in the document. Alternatively, one can also build a document-term matrix by swapping row and column. In this section, we build a term-document matrix from the above processed corpus with function TermDocumentMatrix(). With its default setting, terms with less than three characters are discarded. To keep "r" in the matrix, we set the range of wordLengths in the example below.

```
> myTdm <- TermDocumentMatrix(myCorpus, control = list(wordLengths=c(1,Inf)))
> myTdm
A term-document matrix (444 terms, 154 documents)
```

Non-/sparse entries: 1085/67291

Sparsity : 98%
Maximal term length: 27

Weighting : term frequency (tf)

As we can see from the above result, the term-document matrix is composed of 444 terms and 154 documents. It is very spase, with 98% of the entries being zero. We then have a look at the first six terms starting with "r" and tweets numbered 101 to 110.

```
> idx <- which(dimnames(myTdm)$Terms == "r")
> inspect(myTdm[idx+(0:5),101:110])
A term-document matrix (6 terms, 10 documents)
```

Non-/sparse entries: 9/51 Sparsity: 85% Maximal term length: 12

Weighting : term frequency (tf)

## Docs

| rapidminer   | 1   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| rdatamining  | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 1   | 0   | 0   |

Note that the paremeter to control word length used to be minWordLength prior to version 0.5-7 of package tm. The code to set the minimum word length for old versions of tm is below.

```
> myTdm <- TermDocumentMatrix(myCorpus, control = list(minWordLength=1))</pre>
```

The list of terms can be retrieved with rownames(myTdm). Based on the above matrix, many data mining tasks can be done, for example, clustering, classification and association analysis.

When there are too many terms, the size of a term-document matrix can be reduced by selecting terms that appear in a minimum number of documents, or filtering terms with TF-IDF (term frequency-inverse document frequency) [Wu et al., 2008].

## 10.5 Frequent Terms and Associations

We have a look at the popular words and the association between words. Note that there are 154 tweets in total.

```
> # inspect frequent words
> findFreqTerms(myTdm, lowfreq=10)
```

```
[1] "analysis" "computing" "data" "examples"
[5] "introduction" "mining" "network" "package"
[9] "positions" "postdoctoral" "r" "research"
[13] "slides" "social" "tutorial" "users"
```

In the code above, findFreqTerms() finds frequent terms with frequency no less than ten. Note that they are ordered alphabetically, instead of by frequency or popularity.

To show the top frequent words visually, we next make a barplot of them. From the term-document matrix, we can derive the frequency of terms with rowSums(). Then we select terms that appears in ten or more documents and shown them with a barplot using package ggplot2 [Wickham, 2009]. In the code below, geom="bar" specifies a barplot and coord\_flip() swaps x- and y-axis. The barplot in Figure 10.1 clearly shows that the three most requrent words are "r", "data" and "mining".

> termFrequency <- rowSums(as.matrix(myTdm))
> termFrequency <- subset(termFrequency, termFrequency>=10)
> library(ggplot2)
> qplot(names(termFrequency), termFrequency, geom="bar") + coord\_flip()

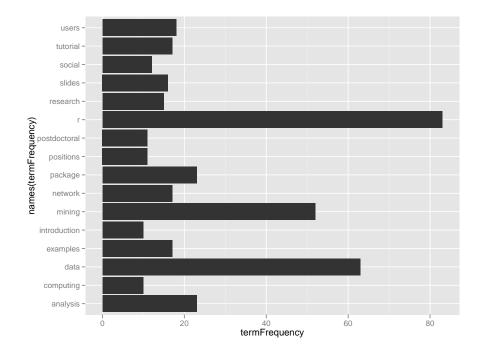

Figure 10.1: Frequent Terms

Alternatively, the above plot can also be drawn with barplot() as below, where las sets the direction of x-axis labels to be vertical.

### > barplot(termFrequency, las=2)

We can also find what are highly associated with a word with function findAssocs(). Below we try to find terms associated with "r" (or "mining") with correlation no less than 0.25, and the words are ordered by their correlation with "r" (or "mining").

- > # which words are associated with "mining"?
- > findAssocs(myTdm, 'mining', 0.25)

10.6. WORD CLOUD 95

| ${\tt recommendation}$ | mahout    | data      | mining |

| itemset                | frequent  | supports  | sets   |
| 0.34                   | 0.35      | 0.39      | 0.39   |
| text                   | reference | functions | card   |
| 0.26                   | 0.29      | 0.29      | 0.29   |

#### 10.6 Word Cloud

After building a term-document matrix, we can show the importance of words with a word cloud (also known as a tag cloud), which can be easily produced with package wordcloud [Fellows, 2012]. In the code below, we first convert the term-document matrix to a normal matrix, and then calculate word frequencies. After that, we set gray levels based on word frequency and use wordcloud() to make a plot for it. With wordcloud(), the first two parameters give a list of words and their frequencies. Words with frequency below three are not plotted, as specified by min.freq=3. By setting random.order=F, frequent words are plotted first, which makes them appear in the center of cloud. We also set the colors to gray levels based on frequency. A colorful cloud can be generated by setting colors with rainbow().

```
> library(wordcloud)
> m <- as.matrix(myTdm)
> # calculate the frequency of words and sort it descendingly by frequency
> wordFreq <- sort(rowSums(m), decreasing=TRUE)
> # word cloud
> set.seed(375) # to make it reproducible
> grayLevels <- gray( (wordFreq+10) / (max(wordFreq)+10) )
> wordcloud(words=names(wordFreq), freq=wordFreq, min.freq=3, random.order=F, colors=grayLevels)
```

Figure 10.2: Word Cloud

The above word cloud clearly shows again that "r", "data" and "mining" are the top three words, which validates that the @RDataMining tweets present information on R and data mining. Some other important words are "analysis", "examples", "slides", "tutorial" and "package", which shows that it focuses on documents and examples on analysis and R packages. Another set of frequent words, "research", "postdoctoral" and "positions", are from tweets about vacancies on post-doctoral and research positions. There are also some tweets on the topic of social network analysis, as indicated by words "network" and "social" in the cloud.

## 10.7 Clustering Words

We then try to find clusters of words with hierarchical clustering. Sparse terms are removed, so that the plot of clustering will not be crowded with words. Then the distances between terms are calculated with dist() after scaling. After that, the terms are clusterd with hclust() and the dendogram is cut into 10 clusters. The agglomeration method is set to ward, which denotes the increase in variance when two clusters are merged. Some other options are single linkage, complete linkage, average linkage, median and centroid. Details about different agglomeration methods can be found in data mining text books [Han and Kamber, 2000, Hand et al., 2001, Witten and Frank, 2005].

```
> # remove sparse terms
> myTdm2 <- removeSparseTerms(myTdm, sparse=0.95)
> m2 <- as.matrix(myTdm2)
> # cluster terms
> distMatrix <- dist(scale(m2))
> fit <- hclust(distMatrix, method="ward")</pre>

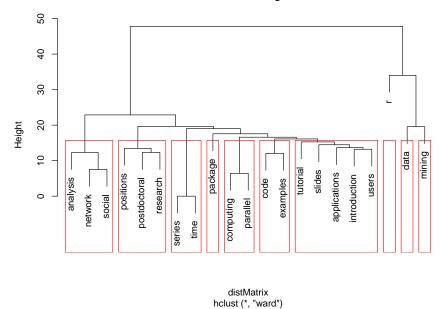

Figure 10.3: Clustering of Words

In the above dendrogram, we can see the topics in the tweets. Words "analysis", "network" and "social" are clustered into one group, because there are a couple of tweets on social network analysis. The second cluster from left comprises "positions", "postdoctoral" and "research", and they are clustered into one group because of tweets on vacancies of research and postdoctoral positions. We can also see cluster on time series, R packages, parallel computing, R codes and examples, and tutorial and slides. The rightmost three clusters consists of "r", "data" and "mining", which are the keywords of @RDataMining tweets.

#### Clustering Tweets 10.8

Tweets are clustered below with the k-means and the k-medoids algorithms.

#### 10.8.1 Clustering Tweets with the k-means Algorithm

We first try k-means clustering, which takes the values in the matrix as numeric. We transpose the term-document matrix to a document-term one. The tweets are then clustered with kmeans() with the number of clusters set to eight. After that, we check the popular words in every cluster and also the cluster centers. Note that a fixed random seed is set with set.seed() before running kmeans(), so that the clustering result can be reproduced. It is for the convenience of book writing, and it is unnecessary for readers to set a random seed.

```
> # transpose the matrix to cluster documents (tweets)
> m3 <- t(m2)
> # set a fixed random seed
> set.seed(122)
> # k-means clustering of tweets
> k <- 8
> kmeansResult <- kmeans(m3, k)</pre>
> # cluster centers
> round(kmeansResult$centers, digits=3)

```

To make it easy to find what the clusters are about, we then check the top three words in every cluster.

```
> for (i in 1:k) {
+ cat(paste("cluster ", i, ": ", sep=""))
+ s <- sort(kmeansResult$centers[i,], decreasing=T)
+ cat(names(s)[1:3], "\n")
+ # print the tweets of every cluster</pre>
```

```
+ # print(rdmTweets[which(kmeansResult$cluster==i)])
+ }

cluster 1: r examples code
cluster 2: data mining r
cluster 3: network analysis social
cluster 4: computing r parallel
cluster 5: data mining tutorial
cluster 6: package r examples
cluster 7: r analysis slides
cluster 8: research data positions
```

From the above top words and centers of clusters, we can see that the clusters are of different topics. For instance, cluster 1 focuses on R codes and examples, cluster 2 on data mining with R, cluster 4 on parallel computing in R, cluster 6 on R packages and cluster 7 on slides of time series analysis with R. We can also see that, all clusters, except for cluster 3, 5 & 8, focus on R. Cluster 3, 5 & 8 are about general information on data mining and are not limited to R. Cluster 3 is on social network analysis, cluster 5 on data mining tutorials, and cluster 8 on positions for data mining research.

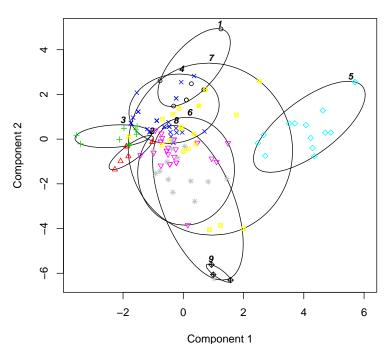

#### 10.8.2 Clustering Tweets with the k-medoids Algorithm

We then try k-medoids clustering with the Partitioning Around Medoids (PAM) algorithm, which uses medoids (representative objects) instead of means to represent clusters. It is more robust to noise and outliers than k-means clustering, and provides a display of the silhouette plot to show the quality of clustering. In the example below, we use function pamk() from package fpc [Hennig, 2010], which calls the function pam() with the number of clusters estimated by optimum average silhouette.

```
> library(fpc)
> # partitioning around medoids with estimation of number of clusters
> pamResult <- pamk(m3, metric = "manhattan")</pre>
> # number of clusters identified
> (k <- pamResult$nc)</pre>
[1] 9
> pamResult <- pamResult$pamobject
> # print cluster medoids
> for (i in 1:k) {
   cat(paste("cluster", i, ": "))
    cat(colnames(pamResult$medoids)[which(pamResult$medoids[i,]==1)], "\n")
    # print tweets in cluster i
    # print(rdmTweets[pamResult$clustering==i])
cluster 1: data positions research
cluster 2 : computing parallel r
cluster 3: mining package r
cluster 4: data mining
cluster 5 : analysis network social tutorial
cluster 6 : r
cluster 7:
cluster 8 : examples r
cluster 9: analysis mining series time users
```

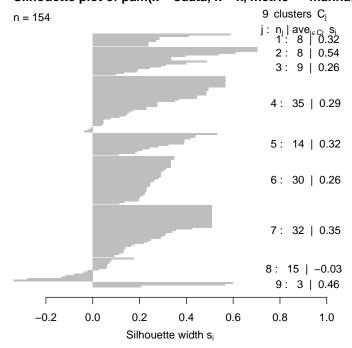

- > # plot clustering result
- > layout(matrix(c(1,2),2,1)) # set to two graphs per page
- > plot(pamResult, color=F, labels=4, lines=0, cex=.8, col.clus=1,
- + col.p=pamResult\$clustering)
- > layout(matrix(1)) # change back to one graph per page

### clusplot(pam(x = sdata, k = k, metric = "manhattan"))

These two components explain 24.81 % of the point variability.

#### Silhouette plot of pam(x = sdata, k = k, metric = "manhat")

Average silhouette width: 0.29

Figure 10.4: Clusters of Tweets

In Figure 10.4, the first chart is a 2D "clusplot" (clustering plot) of the k clusters, and the second one shows their silhouettes. With the silhouette, a large  $s_i$  (almost 1) suggests that the corresponding observations are very well clustered, a small  $s_i$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s_i$  are probably placed in the wrong cluster. The average silhouette width is 0.29, which suggests that the clusters are not well separated from one another.

The above results and Figure 10.4 show that there are nine clusters of tweets. Clusters 1, 2, 3, 5 and 9 are well separated groups, with each of them focusing on a specific topic. Cluster 7 is composed of tweets not fitted well into other clusters, and it overlaps all other clusters. There is also a big overlap between cluster 6 and 8, which is unstandable from their medoids. Some observations in cluster 8 are of negative silhouette width, which means that they may fit better in other clusters than cluster 8.

To improve the clustering quality, we have also tried to set the range of cluster numbers krange=2:8 when calling pamk(), and in the new clustering result, there are eight clusters, with the observations in the above cluster 8 assigned to other clusters, mostly to cluster 6. The results are not shown in this book, and the readers can try it with the code below.

> pamResult2 <- pamk(m3, krange=2:8, metric = "manhattan")</pre>

### 10.9 Packages, Further Readings and Discussions

Some R packages for text mining are listed below.

- Package tm [Feinerer, 2012]: A framework for text mining applications within R.
- Package *tm.plugin.mail* [Feinerer, 2010]: Text Mining E-Mail Plug-In. A plug-in for the tm text mining framework providing mail handling functionality.
- package textcat [Hornik et al., 2012] provides n-Gram Based Text Categorization.
- lda [Chang, 2011] fit topic models with LDA (latent Dirichlet allocation)
- topic models [Grün and Hornik, 2011] fit topic models with LDA and CTM (correlated topics model)

For more information and examples on text mining with R, some online resources are:

- Introduction to the tm Package Text Mining in R http://cran.r-project.org/web/packages/tm/vignettes/tm.pdf
- Text Mining Infrastructure in R [Feinerer et al., 2008] http://www.jstatsoft.org/v25/i05
- Text Mining Handbook http://www.casact.org/pubs/forum/10spforum/Francis\_Flynn.pdf
- Distributed Text Mining in R http://epub.wu.ac.at/3034/
- Text mining with Twitter and R http://heuristically.wordpress.com/2011/04/08/text-data-mining-twitter-r/

In addition to frequent terms, associations and clustering demonstrated in this chapter, some other possible analysis on the above Twitter text is graph mining and social network analysis. For example, a graph of words can be derived from a document-term matrix, and then we can use techniques for graph mining to find links between words and groups of words. A graph of tweets (documents) can also be generated and analyzed in a similar way. It can also be presented and analyzed as a bipartite graph with two disjoint sets of vertices, that is, words and tweets. We will demonstrate social network analysis on the Twitter data in Chapter 11: Social Network Analysis.

## Chapter 11

# Social Network Analysis

This chapter presents examples of social network analysis with R, specifically, with package *igraph* [Csardi and Nepusz, 2006]. The data to analyze is Twitter text data used in Chapter 10: Text Mining. Putting it in a general scenario of social networks, the terms can be taken as people and the tweets as groups on LinkedIn<sup>1</sup>, and the term-document matrix can then be taken as the group membership of people.

In this chapter, we will first build a network of terms based on their co-occurrence in the same tweets, and then build a network of tweets based on the terms shared by them. At last, we will build a two-mode network composed of both terms and tweets. We will also demonstrate some tricks to plot nice network graphs. Some codes in this chapter are based on the examples at http://www.stanford.edu/~messing/Affiliation%20Data.html.

#### 11.1 Network of Terms

In this section, we will build a network of terms based on their co-occurrence in tweets. At first, a term-document matrix, termDocMatrix, is loaded into R, which is actually a copy of m2, an R object from Chapter 10: Text Mining. After that, it is transformed into a term-term adjacency matrix, based on which a graph is built. Then we plot the graph to show the relationship between frequent terms, and also make the graph more readable by setting colors, font sizes and transparency of vertices and edges.

- > # load termDocMatrix
- > load("data/termDocMatrix.rdata")
- > # inspect part of the matrix
- > termDocMatrix[5:10,1:20]

| I            | Dod | cs |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |
|--------------|-----|----|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
| Terms        | 1   | 2  | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
| data         | 1   | 1  | 0 | 0 | 2 | 0 | 0 | 0 | 0 | 0  | 1  | 2  | 1  | 1  | 1  | 0  | 1  | 0  | 0  | 0  |

- > # change it to a Boolean matrix
- > termDocMatrix[termDocMatrix>=1] <- 1</pre>
- > # transform into a term-term adjacency matrix
- > termMatrix <- termDocMatrix %\*% t(termDocMatrix)

<sup>1</sup>http://www.linkedin.com

- > # inspect terms numbered 5 to 10
- > termMatrix[5:10,5:10]

> V(g)\$degree <- degree(g)

|              | Terms |          |                      |        |                 |         |
|--------------|-------|----------|----------------------|--------|-----------------|---------|
| Terms        | data  | examples | ${\tt introduction}$ | mining | ${\tt network}$ | package |
| data         | 53    | 5        | 2                    | 34     | 0               | 7       |
| examples     | 5     | 17       | 2                    | 5      | 2               | 2       |
| introduction | 2     | 2        | 10                   | 2      | 2               | 0       |
| mining       | 34    | 5        | 2                    | 47     | 1               | 5       |
| network      | 0     | 2        | 2                    | 1      | 17              | 1       |
| package      | 7     | 2        | 0                    | 5      | 1               | 21      |

In the above code, %\*% is an operator for the product of two matrices, and t() transposes a matrix. Now we have built a term-term adjacency matrix, where the rows and columns represents terms, and every entry is the number of cooccurrences of two terms. Next we can build a graph with graph.adjacency() from package *igraph*.

```
> library(igraph)
> # build a graph from the above matrix
> g <- graph.adjacency(termMatrix, weighted=T, mode = "undirected")
> # remove loops
> g <- simplify(g)
> # set labels and degrees of vertices
> V(g)$label <- V(g)$name</pre>
```

After that, we plot the network with layout.fruchterman.reingold.

- > # set seed to make the layout reproducible
- > set.seed(3952)
- > layout1 <- layout.fruchterman.reingold(g)</pre>
- > plot(g, layout=layout1)

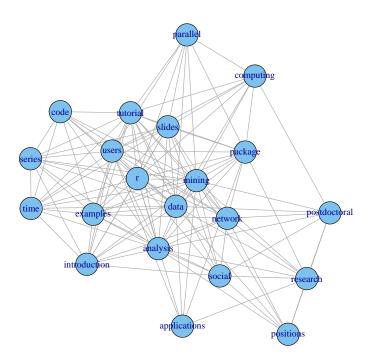

Figure 11.1: A Network of Terms - I

In the above code, the layout is kept as layout1, so that we can plot the graph in the same layout later.

A different layout can be generated with the first line of code below. The second line produces an interactive plot, which allows us to manually rearrange the layout. Details about other layout options can be obtained by running <code>?igraph::layout</code> in R.

> plot(g, layout=layout.kamada.kawai)
> tkplot(g, layout=layout.kamada.kawai)

We can also save the network graph into a .PDF file with the code below.

> pdf("term-network.pdf")
> plot(g, layout=layout.fruchterman.reingold)
> dev.off()

Next, we will set the label size of vertices based on their degrees, to make important terms stand out. Similarly, we also set the width and transparency of edges based on their weights. This is useful in applications where graphs are crowded with many vertices and edges. In the code below, the vertices and edges are accessed with V() and E(). Function rgb(red, green, blue,

alpha) defines a color, with an alpha transparency. We plot the graph in the same layout as Figure 11.1.

```
> V(g)$label.cex <- 2.2 * V(g)$degree / max(V(g)$degree)+ .2
> V(g)$label.color <- rgb(0, 0, .2, .8)
> V(g)$frame.color <- NA
> egam <- (log(E(g)$weight)+.4) / max(log(E(g)$weight)+.4)
> E(g)$color <- rgb(.5, .5, 0, egam)
> E(g)$width <- egam
> # plot the graph in layout1
> plot(g, layout=layout1)
```

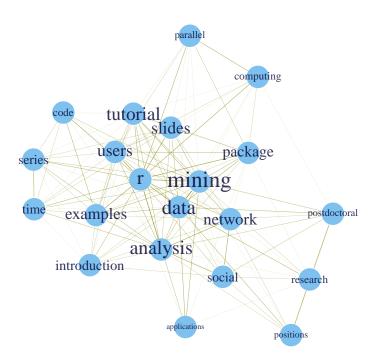

Figure 11.2: A Network of Terms - II

#### 11.2 Network of Tweets

Similar to the previous section, we can also build a graph of tweets base on the number of terms that they have in common. Because most tweets contain one or more words from "r", "data" and "mining", most tweets are connected with others and the graph of tweets is very crowded. To simplify the graph and find relationship between tweets beyond the above three keywords, we remove the three words before building a graph.

```
> # remove "r", "data" and "mining"
> idx <- which(dimnames(termDocMatrix)$Terms %in% c("r", "data", "mining"))</pre>
```

```
> M <- termDocMatrix[-idx,]
> # build a tweet-tweet adjacency matrix
> tweetMatrix <- t(M) %*% M
> library(igraph)
> g <- graph.adjacency(tweetMatrix, weighted=T, mode = "undirected")
> V(g)$degree <- degree(g)
> g <- simplify(g)
> # set labels of vertices to tweet IDs
> V(g)$label <- V(g)$name
> V(g)$label.cex <- 1
> V(g)$label.color <- rgb(.4, 0, 0, .7)
> V(g)$size <- 2
> V(g)$frame.color <- NA</pre>
```

Next, we have a look at the distribution of degree of vertices. From Figure 11.3, we can see that there are around 40 isolated vertices (with a degree of zero). Note that most of them are caused by the removal of the three keywords.

#### > barplot(table(V(g)\$degree))

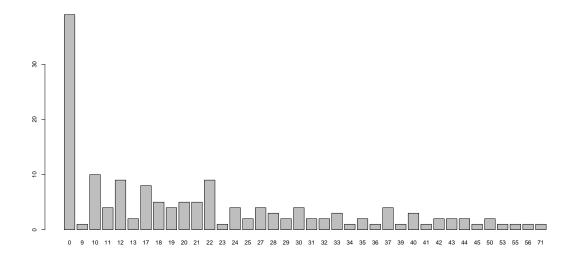

Figure 11.3: Distribution of Degree

In the code below, we set vertex colors based on degree, and set labels of isolated vertices to tweet IDs and the first 20 characters of every tweet. The labels of other vertices are set to tweet IDs only, so that the graph will not be overcrowded with labels. We also set the color and width of edges based on their weights.

```
> idx <- V(g)$degree == 0
> V(g)$label.color[idx] <- rgb(0, 0, .3, .7)
> # set labels to the IDs and the first 10 characters of tweets
> V(g)$label[idx] <- paste(V(g)$name[idx], substr(df$text[idx], 1, 20), sep=": ")
> egam <- (log(E(g)$weight)+.2) / max(log(E(g)$weight)+.2)
> E(g)$color <- rgb(.5, .5, 0, egam)
> E(g)$width <- egam</pre>
```

```
> set.seed(3152)
> layout2 <- layout.fruchterman.reingold(g)
> plot(g, layout=layout2)
```

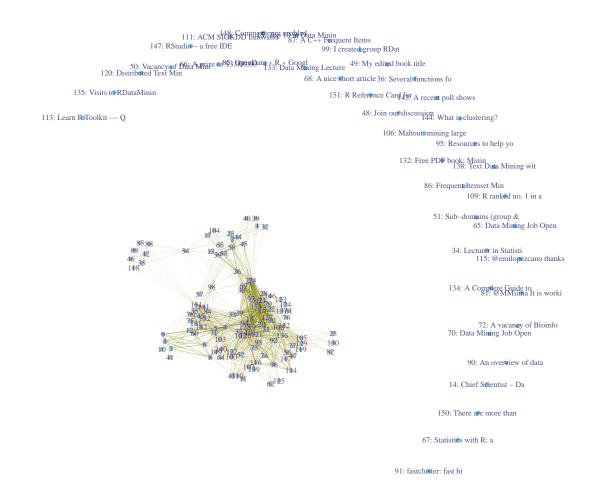

Figure 11.4: A Network of Tweets - I

The vertices in crescent are isolated from all others, and next we remove them from graph with function delete.vertices().

> plot(g2, layout=layout.fruchterman.reingold)

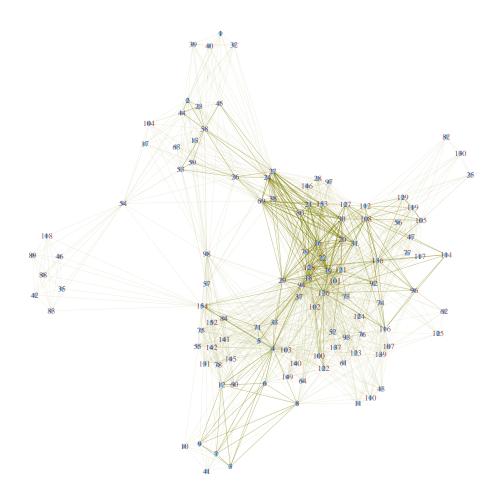

Figure 11.5: A Network of Tweets - II

Similarly, we can also remove edges with low degrees to simplify the graph. Below with function delete.edges(), we remove edges which have weight of one. After removing edges, some vertices become isolated and are also removed.

```
> g3 <- delete.edges(g, E(g)[E(g)$weight <= 1])
> g3 <- delete.vertices(g3, V(g3)[degree(g3) == 0])</pre>
```

> plot(g3, layout=layout.fruchterman.reingold)

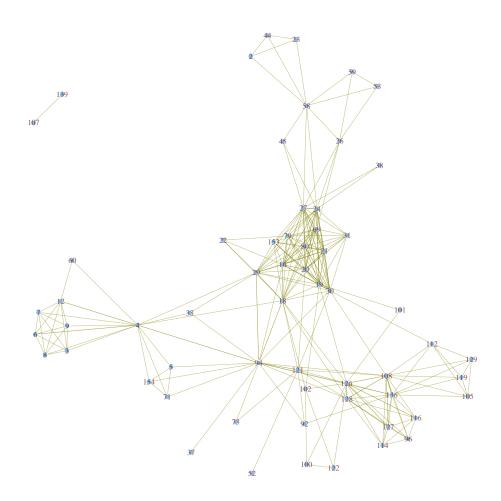

Figure 11.6: A Network of Tweets - III

In Figure 11.6, there are some groups (or cliques) of tweets. Let's have a look at the group in the middle left of the figure.

#### > df\$text[c(7,12,6,9,8,3,4)]

- [7] State of the Art in Parallel Computing with R http://t.co/zmClglqi
- [12] The R Reference Card for Data Mining is updated with functions & packages for handling big data & parallel computing. http://t.co/FHoVZCyk
- [6] Parallel Computing with R using snow and snowfall http://t.co/nxp8EZpv
- [9] R with High Performance Computing: Parallel processing and large memory  $\verb|http://t.co/XZ3ZZBRF|$

- [3] Easier Parallel Computing in R with snowfall and sfCluster

```
http://t.co/BPcinvzK
[4] Tutorial: Parallel computing using R package snowfall http://t.co/CHBCyr76
```

We can see that tweets 7, 12, 6, 9, 8, 3, 4 are on parallel Computing with R. We can also see some other groups below:

- Tweets 4, 33, 94, 29, 18 and 92: tutorials for R;
- Tweets 4, 5, 154 and 71: R packages;
- Tweets 126, 128, 108, 136, 127, 116, 114 and 96: time series analysis;
- Tweets 112, 129, 119, 105, 108 and 136: R code examples; and
- Tweets 27, 24, 22,153, 79, 69, 31, 80, 21, 29, 16, 20, 18, 19 and 30: social network analysis.

Tweet 4 lies between multiple groups, because it contains keywords "parallel computing", "tutorial" and "package".

### 11.3 Two-Mode Network

In this section, we will build a two-mode network, which is composed of two types of vertices: tweets and terms. At first, we generate a graph g directly from termDocMatrix. After that, different colors and sizes are assigned to term vertices and tweet vertices. We also set the width and color of edges. The graph is then plotted with layout.fruchterman.reingold.

```
> # create a graph
> g <- graph.incidence(termDocMatrix, mode=c("all"))</pre>
> # get index for term vertices and tweet vertices
> nTerms <- nrow(M)</pre>
> nDocs <- ncol(M)</pre>
> idx.terms <- 1:nTerms</pre>
> idx.docs <- (nTerms+1):(nTerms+nDocs)</pre>
> # set colors and sizes for vertices
> V(g)$degree <- degree(g)
> V(g)$color[idx.terms] \leftarrow rgb(0, 1, 0, .5)
> V(g)$size[idx.terms] <- 6</pre>
> V(g)$color[idx.docs] <- rgb(1, 0, 0, .4)
> V(g)$size[idx.docs] <- 4
> V(g)$frame.color <- NA
> # set vertex labels and their colors and sizes
> V(g)$label <- V(g)$name
> V(g)$label.color <- rgb(0, 0, 0, 0.5)
> V(g) $label.cex <- 1.4*V(g)$degree/max(V(g)$degree) + 1
> # set edge width and color
> E(g)$width <- .3
> E(g)$color <- rgb(.5, .5, 0, .3)
```

- > set.seed(958)#5365, 227
- > plot(g, layout=layout.fruchterman.reingold)

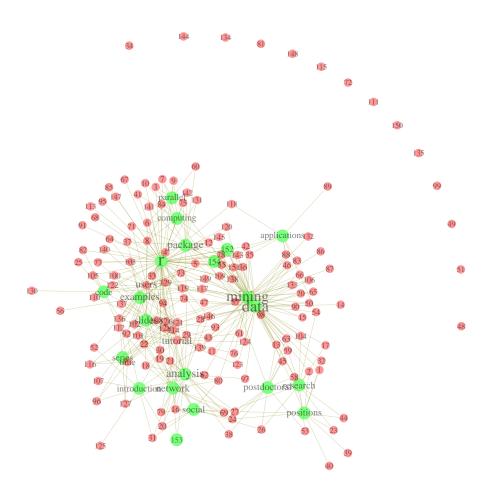

Figure 11.7: A Two-Mode Network of Terms and Tweets - I

The graph above shows that most tweets are around two centers, "r" and "data mining". Next, let's have a look at which tweets are about "r". In the code below, nei("r") returns all vertices which are neighbors of vertex "r".

### > V(g)[nei("r")]

#### Vertex sequence:

[1] "3" "6" [12] "22" "25" "28" "33" "35" "36" "41" "64" "30" "42" "55" "74" "75" "77" "78" "82" "84" [23] "67" "68" "73" "85" [34] "92" "94" "95" "100" "101" "102" "105" "108" "109" "110" "112" [45] "113" "114" "117" "118" "119" "120" "121" "122" "126" "128" "129"

```
[56] "131" "136" "137" "138" "140" "141" "142" "143" "145" "146" "147" [67] "149" "151" "152" "154"
```

An alternative way is using function neighborhood() as below.

```
> V(g)[neighborhood(g, order=1, "r")[[1]]]
```

We can also have a further look at which tweets contain all three terms: "r", "data" and "mining".

```
> (rdmVertices <- V(g)[nei("r") & nei("data") & nei("mining")])</pre>
```

```
Vertex sequence:
[1] "12" "35" "36" "42" "55" "78" "117" "119" "138" "143" "149"
[12] "151" "152" "154"
```

```
> df$text[as.numeric(rdmVertices$label)]
```

- [12] The R Reference Card for Data Mining is updated with functions & packages for handling big data & parallel computing. http://t.co/FHoVZCyk
- [35] Call for reviewers: Data Mining Applications with R. Pls contact me if you have experience on the topic. See details at http://t.co/rcYIXfnp
- [36] Several functions for evaluating performance of classification models added to R Reference Card for Data Mining: http://t.co/FHoVZCyk
- [42] Call for chapters: Data Mining Applications with R, an edited book to be published by Elsevier. Proposal due 30 April. http://t.co/HPaBSbRa
- [55] Some R functions and packages for outlier detection have been added to R Reference Card for Data Mining at http://t.co/FHoVZCyk.

To make it short, only the first five tweets are shown in the result. In the above code, df is a data frame which keeps tweets of RDataMining, and details of it can be found in Section 10.2.

Next, we remove "r", "data" and "mining" to show the relationship between tweets with other words. Isolated vertices are also deleted from graph.

```
> idx <- which(V(g)$name %in% c("r", "data", "mining"))
> g2 <- delete.vertices(g, V(g)[idx-1])
> g2 <- delete.vertices(g2, V(g2)[degree(g2)==0])
> set.seed(209)
> plot(g2, layout=layout.fruchterman.reingold)
```

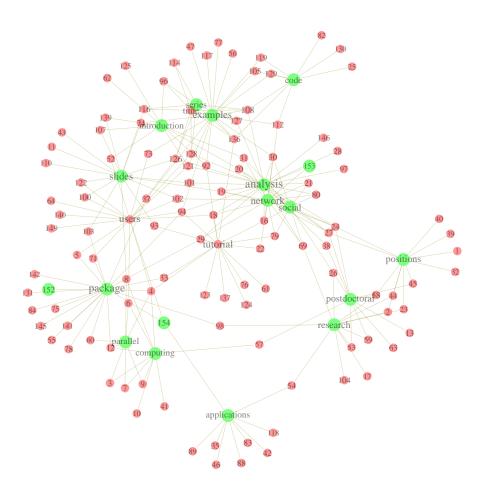

Figure 11.8: A Two-Mode Network of Terms and Tweets - II

From Figure 11.8, we can clearly see groups of tweets and their keywords, such as time series, social network analysis, parallel computing and postdoctoral and research positions, which are similar to the result obtained at the end of Section 11.2.

### 11.4 Discussions and Further Readings

In this chapter, we have demonstrated how to find groups of tweets and some topics in the tweets with package *igraph*. Similar analysis can also be done with package *sna* [Butts, 2010]. There

are also packages designed for topic modelling, such as package *lda* [Chang, 2011] and package *topicmodels* [Grün and Hornik, 2011].

For readers interested in social network analysis with R, there are some further readings. Some examples on social network analysis with the *igraph* package [Csardi and Nepusz, 2006] are available as tutorial on *Network Analysis with Package igraph* at http://igraph.sourceforge.net/igraphbook/ and R for Social Network Analysis at http://www.stanford.edu/~messing/RforSNA.html. There is a detailed introduction to Social Network Analysis with package *sna* [Butts, 2010] at http://www.jstatsoft.org/v24/i06/paper. A *statnet* Tutorial is available at http://www.jstatsoft.org/v24/i09/paper and more resources on using *statnet* [Handcock et al., 2003] for network analysis can be found at http://csde.washington.edu/statnet/resources.shtml. There is a short tutorial on package *network* [Butts et al., 2012] at http://sites.stat.psu.edu/~dhunter/Rnetworks/. Slides on Social network analysis with R *sna* package can be found at http://user2010.org/slides/Zhang.pdf. slides on Social Network Analysis in R can be found at http://files.meetup.com/1406240/sna\_in\_R.pdf. Some R codes for community detection are available at http://igraph.wikidot.com/community-detection-in-r.
