About the Authors

Raymond Camden is a Developer Evangelist for Adobe focusing on web standards and mobile development. He is a contributing author to numerous technical books including the best selling *ColdFusion Web Application Construction Kit*, published by *Adobe Press*. He has spoken at conferences around the world and maintains many popular ColdFusion community websites. He is the manager of www.RIAForge.org, www.CFLib.org, and writes at his blog www.raymondcamden.com. Raymond is happily married and a proud father to three kids and is somewhat of a Star Wars nut.

I'd like to thank everyone on the jQuery and jQuery Mobile teams for making tools that have changed my life. Without your hard work and dedication, the web would be less awesome. Thank you Andy, for coming on board and helping to make this book better.

Andy Matthews has been working as a web and application developer for 13 years, with an experience in a wide range of industries, and has a skill set which includes graphic design, programming, business strategy and planning, and marketing. Throughout his career he has been privileged to work on projects which interfaced with industry giants such as Craigslist, written code that allowed Enterprise level sales teams to quickly and efficiently build presentations for their clients. He stays up-to-date with current trends in the marketplace by helping previous employers transition to newer, more effective, coding habits and standards. He is a frequent speaker at conferences around the country. He has also developed software for the open source community, and he currently works for a social networking startup Goba.mobi in Nashville, TN.

I'd like to thank my wife Jaime, and my children Noelle, Evan, and Mason for their patience and grace in letting me pursue my passion. Most of all, thank you God for giving me the desire to learn, the ability to pick things up quickly, and the perseverance to apply the knowledge I've gained throughout the years.

About the Reviewers

Md Mahmud Ahsan has been developing and leading some medium to large web applications for the past six years. He has worked with a number of PHP frameworks (Zend, CodeIgniter) and generally likes working with an MVC design pattern. His experience ranges from developing web applications from scratch, as well as modifying and adding functionality to existing custom in-house systems, open source applications, and commercial applications. He graduated in Computer Science and Engineering, and is a PHP5 Zend Certified Engineer. He is also an expert in iPhone applications development and has in depth working knowledge in Objective C, C, C++, Cocos2D, Box2D, and Xcode. Apart from his full time job, he maintains a blog at <http://thinkdiff.net>. He lives in Bangladesh with his wife Jinat Jahan.

Currently, he is self employed and has been developing iPhone and iPad applications, which he publishes through his own site <http://ithinkdiff.net>. Besides this, he is a part time freelancer and works on LAMP based web applications development.

He was a technical reviewer for the following books published by *Packt Publishing*:

- *Zend Framework 1.8 Web Application Development Book*
- *PHP jQuery Cookbook*
- *jQuery UI themes*
- *Android 3.0 Application Development Cookbook*

I'm very grateful to my father who brought a computer for me in 2001, since then I have loved programming and work in various technologies.

Shameemah Kurzawa started programming when she was at high school. Being motivated to be a System Analyst, she pursued both undergraduate and postgraduate studies in Business Information Systems and Software Engineering respectively.

She has been working as a Web Developer/Analyst for the past six years; she has worked in the past for Australia's renowned broadcasting company SBS and has freelanced for her own company since 2010. Besides work she enjoys spending time with her family, traveling, and cooking. She likes to read and try new web technologies.

She has previously reviewed *jQuery UI themes* and *PHP jQuery Cookbook* for Packt Publishing.

I would like to thank my husband and the Packt team for their support and understanding in helping me review this book.

M. Ali Qureshi is based in Lahore, Pakistan. He has developed a comprehensive understanding of web development processes having worked in the capacity of Web Designer, Frontend developer, PHP Developer, Flash ActionScript Developer, Software Engineer, and Project Manager in the last 12 years designing and developing creative, interactive and usable web solutions, that get high rankings in search engines and drive qualified traffic to websites, making them a successful technology investment.

He has done a Masters in Economics and Computer Sciences. Running along Lahore canal early in the morning, watching good movies and listening to music, working out at the gym, reading books, discussing politics, and an occasional stroll in Lawrence Garden, Lahore are a few things that Ali mostly enjoys.

When not working, he spends his time blogging and exploring new technologies. Ali is an avid sports fan and likes watching Cricket, especially Pakistan and Australia which are his favorite teams.

Joe Wu is a Senior PHP Web Developer and has more than four years of commercial experience to date.

Joe is always enthusiastic about exploring new ideas, technologies and opportunities that arise. He has a wide range of skills, specializing primarily in PHP, CodeIgniter PHP Framework, MySQL, JQuery, HTML, and CSS. Joe's skills and experiences further extends out to various other technologies and tools such as Subversion, Microsoft CRM, SOAP, Bash Scripting, and Symfony PHP Framework.

Joe is also a professional Badminton player, achieving the highest ranking of 59 in the world in singles and top ranking in Australasia in 2010.

If you would like to get in touch with Joe to discuss any opportunities please do not hesitate to visit his personal website: <http://www.joewu.net/>.

Do you need instant solutions to your IT questions? PacktLib is Packt's online digital book library. Here, you can access, read and search across Packt's entire library of books.

Why Subscribe?

- Fully searchable across every book published by Packt
- Copy and paste, print and bookmark content
- On demand and accessible via web browser

Free Access for Packt account holders

If you have an account with Packt at www.PacktPub.com, you can use this to access PacktLib today and view nine entirely free books. Simply use your login credentials for immediate access.

To my wife Jeanne. Thank you for always being there. Thank you for making me feel like I could do this. Thank you being strong when I'm weak. Thank you for everything.

-Raymond Camden

Table of Contents

Preface	1
Chapter 1: Preparing your First jQuery Mobile Project	11
Important preliminary points	11
Building an HTML page	11
Getting jQuery Mobile	13
Implementing jQuery Mobile	14
Working with data attributes	16
Summary	18
Chapter 2: Working with jQuery Mobile Pages	19
Important preliminary points	19
Adding multiple pages to one file	20
jQuery Mobile, links, and you	22
Working with multiple files	23
jQuery Mobile and URLs	26
Additional customization	26
Page titles	27
Prefetching content	28
Changing page transitions	28
Summary	29
Chapter 3: Enhancing Pages with Headers, Footers, and Toolbars	31
Important preliminary points	31
Adding headers	31
Icon sneak peak	34
Working with back buttons	34
Working with footers	36
Creating fixed and full screen headers and footers	38
Full screen positioning	39
Working with navigation bars	40
Persisting navigation bar footers across multiple pages	42

Summary	44
Chapter 4: Working with Lists	45
Creating lists	45
Working with list feature	50
Creating Inset lists	51
Creating list dividers	52
Creating lists with count bubbles	53
Using thumbnails and icons	54
Creating Split Button lists	56
Using a search filter	57
Summary	58
Chapter 5: Getting Practical – Building a Simple Hotel Mobile Site	59
Welcome to Hotel Camden	59
The home page	60
Finding the hotel	62
Listing the hotel rooms	65
Contacting the hotel	68
Summary	70
Chapter 6: Working with Forms and jQuery Mobile	71
Before you begin	71
What jQuery Mobile does with forms	72
Working with radio buttons and checkboxes	76
Working with select menus	79
Search, toggle, and slider fields	82
Search fields	83
Flip toggle fields	83
Slider fields	84
Using native form controls	85
Working with "mini" fields	85
Summary	86
Chapter 7: Creating Modal Dialogs, Grids, and Collapsible Blocks	87
Creating dialogs	87
Laying out content with grids	91
Working with collapsible content	97
Summary	102
Chapter 8: jQuery Mobile Configuration, Utilities, and JavaScript methods	103
Configuring jQuery Mobile	103
Using jQuery Mobile utilities	109
Page methods and utilities	109

Path and URL related utilities	111
Miscellaneous utilities	115
jQuery widget and form utilities	115
Summary	119
Chapter 9: Working with Events	121
Working with physical events	121
Handling page events	129
What about \$(document).ready?	133
Creating a real example	133
Summary	136
Chapter 10: Moving further with the Notekeeper	
Mobile Application	137
What is a mobile application?	137
Designing your first mobile application	138
Listing out the requirements	138
Building your wireframes	139
Designing the add note wireframe	139
Display notes wireframe	140
View note/delete button wireframe	140
Writing the HTML	141
Adding functionality with JavaScript	143
Storing Notekeeper data	146
Using localStorage	146
Effective use of boilerplates	148
Building the Add Note feature	148
Adding bindings	148
Collecting and storing the data	150
Building the Display Notes feature	151
Dynamically adding notes to our listview	153
Viewing a note	154
Using the Live function	154
Dynamically creating a new page	155
Deleting a note	157
Summary	158
Chapter 11: Enhancing jQuery Mobile	159
What's possible?	159
The visual building blocks of jQuery Mobile	160
Border-radius	161
Applying drop shadows	162
Using text-shadow	163
Using box-shadow	164

Index	219

Preface

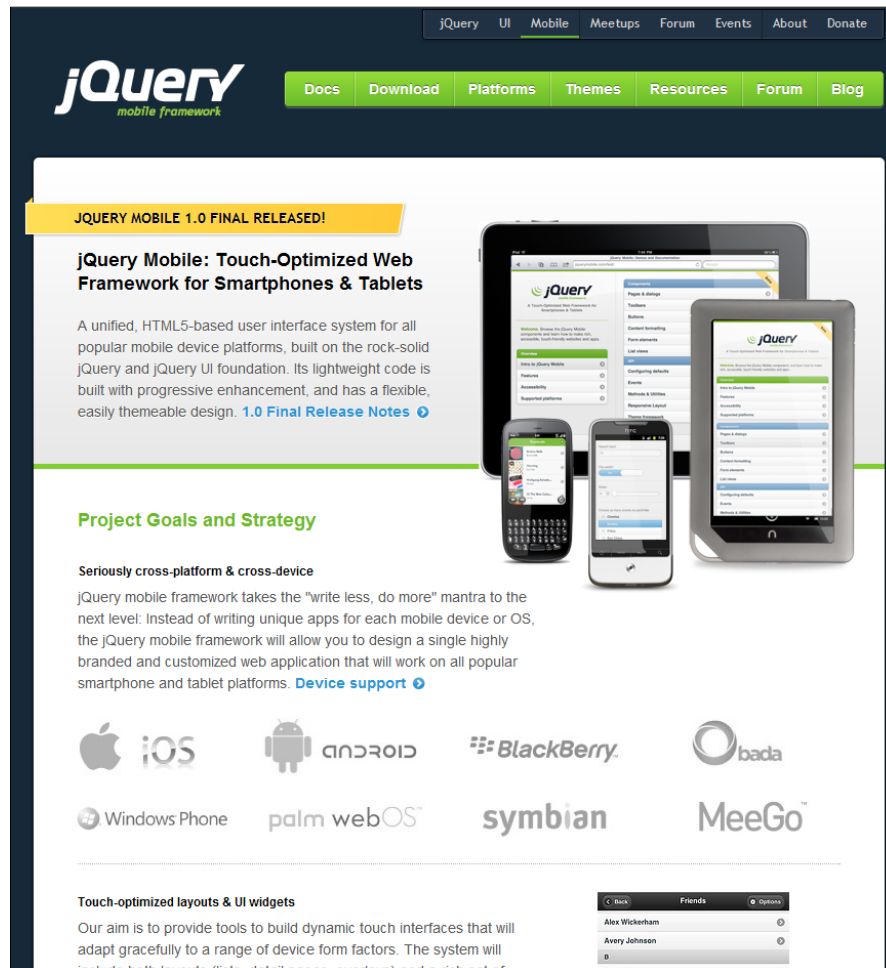

What is jQuery Mobile?

On August 11, 2010, nearly two years ago, John Resig (creator of jQuery) announced the jQuery Mobile project. While focused on the UI framework, it was also a recognition of jQuery itself as a tool for mobile sites and that work would be done to the core framework itself, to make it work better on devices. Release after release, the jQuery Mobile project evolved into a powerful framework encompassing more platforms, more features, and better performance with every update.

But what do we mean when we say a *UI framework*? What does it mean for developers and designers? jQuery Mobile provides a way to turn regular HTML (and CSS) into mobile friendly sites. As you will see soon in the first chapter, you can take a regular HTML page, add in the required bits for jQuery Mobile (essentially five lines of HTML), and find your page transformed into a mobile-friendly version instantly.

Unlike other frameworks, jQuery Mobile is focused on HTML. In fact, for a framework tied to jQuery, you can do a heck of a lot of work without writing one line of JavaScript. It's a powerful, practical way of creating mobile websites that any existing HTML developer can pick up and adapt within a few hours. Compare this to other frameworks, such as Sencha Touch. Sencha Touch is also a powerful framework, but its approach is radically different, using JavaScript to help define and layout pages. jQuery Mobile is much friendlier to people who are more familiar with HTML, as opposed to JavaScript. jQuery Mobile is *touch friendly*, which will make sense to anyone who has used a smart phone and struggled to click the exact right spot on a website with tiny text and hard to spot links. It will make sense to anyone who accidentally clicked on a Reset button instead of Submit. jQuery Mobile will enhance your content to help solve these issues. Regular buttons become large, fat, and easy to hit buttons. Links can be turned into list based navigation systems. Content can be split into virtual pages with smooth transitions. You will be surprised just how jQuery Mobile works without writing much code at all.

jQuery Mobile has some very big sponsors. They include Nokia, Blackberry, Adobe, and other large companies. These companies have put in money, hardware, and developer resources to help ensure the success of the project:

What's the cost?

Ah, the million dollar question. Luckily this one is easy to answer: nothing. jQuery Mobile, like jQuery itself, is completely free to use for any purpose. Not only that, it's completely open source. Don't like how something works? You can change it. Want something not supported by the framework? You can add it. To be fair, digging deep into the code base is probably something most folks will not be comfortable doing. However, the fact that you can if you need to, and the fact that other people can, leads to a product that will be open to development by the community at large.

What do you need to know?

Finally, along with not paying a dime to get, and work with, jQuery Mobile, the best thing is that you probably already have all the skills necessary to work with the framework. As you will see in the upcoming chapters, jQuery Mobile is an HTML based framework. If you know HTML, even just simple HTML, you can use the jQuery Mobile framework. Knowledge of CSS and JavaScript is a plus, but not entirely required. (While jQuery Mobile uses a lot of CSS and JavaScript behind the scenes, you don't actually have to write any of this yourself!)

What about native apps?

jQuery Mobile does not create native applications. You'll see later in the book how you can combine jQuery Mobile with *wrapper* technologies such as PhoneGap to create native apps but, in general, jQuery Mobile is for building websites. The question on whether to develop a website or a mobile app is not something this book can answer. You need to look at your business needs and see what will satisfy them. Because we are not building mobile apps themselves, you do not have to worry about setting up any accounts with Google or Apple, or paying any fees for the marketplace. Any user with a mobile device that includes a browser will be able to view your mobile-optimized sites.

Again – if you want to develop true mobile apps with jQuery Mobile, it's definitely an option.

Help!

While we'd like to think that this book will cover every single possible topic you would need for all your jQuery Mobile needs, most likely there will be things we can't cover. If you need help, there are a couple of places you can try.

First, the jQuery Mobile docs (<http://jquerymobile.com/demos/1.0/>), cover syntax, features, and development in general, much like this book. While the material may cover some of the same ground, if you find something confusing here, try the official docs. Sometimes a second explanation can really help.

Second, the jQuery Mobile forum (<http://forum.jquery.com/jquery-mobile>), is an open ended discussion list for jQuery Mobile topics. This is the perfect place to ask questions. Also, it's a good place to learn about problems other people are having. You may even be able to help them. One of the best ways to learn a new topic is by helping others.

Examples

Want to see jQuery Mobile in action? There's a site for that. JQM Gallery (<http://www.jqmgallery.com/>), is a collection of sites submitted by users, built using jQuery Mobile. Not surprisingly, this website too uses jQuery Mobile, which makes it yet another way to sample jQuery Mobile:

What this book covers

Chapter 1, Preparing your First jQuery Mobile Project, works you through your first jQuery Mobile project. It details what must be added to your project's directory and source code.

Chapter 2, Working with jQuery Mobile Pages, continues the work in the previous chapter and introduces the concept of jQuery Mobile pages.

Chapter 3, Enhancing Pages with Headers, Footers, and Toolbars, explains how to enhance your pages with nicely formatted headers and footers.

Chapter 4, Working with Lists, describes how to create jQuery Mobile list views. These are mobile optimized lists which are especially great for navigation.

Chapter 5, Getting Practical – Building a Simple Hotel Mobile Site, walks you through creating your first "real" (albeit simple) jQuery Mobile application.

Chapter 6, Working with Forms and jQuery Mobile, explains the process of using jQuery Mobile optimized forms. Layout and special form features are covered in detail.

Chapter 7, Creating Modal Dialogs, Grids, and Collapsible Blocks, walks you through special jQuery Mobile user interface items for creating grid based layouts, dialogs, and collapsible content areas.

Chapter 8, jQuery Mobile Configuration, Utilities, and JavaScript methods, describes the various JavaScript-based utilities your code may have need of.

Chapter 9, Working with Events, details the events thrown by various jQuery Mobile-related features, like pages loading and unloading.

Chapter 10, Moving Further with the Notekeeper Mobile Application, walks you through the process of creating another website, an HTML5-enhanced note taking application.

Chapter 11, Enhancing jQuery Mobile, demonstrates how to change the default appearance of your jQuery Mobile sites by selecting and creating unique themes.

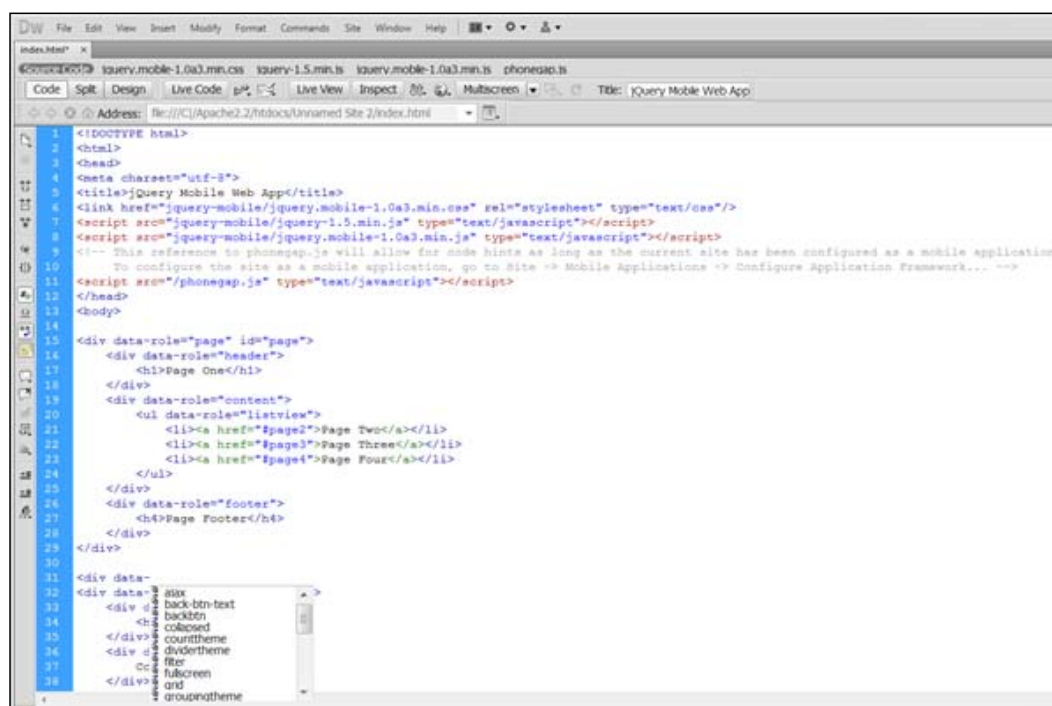

Chapter 12, Creating Native Applications, takes what you've learned previously and shows how to use the open source PhoneGap project to create real native applications.

Chapter 13, Becoming an expert Build an RSS Reader application, expands upon the previous chapter by creating an application that lets you add and read RSS feeds on mobile devices.

What you need for this book

Nothing! Technically you need a computer, and a browser as well, but jQuery Mobile is built with HTML, CSS, and JavaScript. No IDE (Integrated Development Environment) or special tool will be required to work with the framework. If you've got any editor on your system (and all operating systems include a free editor of some sort), you can develop with jQuery Mobile.

There are good IDEs out there that can help you be more productive. For example, Adobe Dreamweaver CS 5.5 includes native support for jQuery Mobile with code assist and device previews:

At the end of the day, you can develop with jQuery Mobile for free. It's zero cost to you to download, develop, and publish jQuery Mobile sites.

Who this book is for

This book is for anyone looking to embrace mobile development and expand their skill set beyond the desktop.

Conventions

In this book, you will find a number of styles of text that distinguish between different kinds of information. Here are some examples of these styles, and an explanation of their meaning.

Code words in text are shown as follows: "Notice the new `data-title` tag added to the `div` tag."

A block of code is set as follows:

```
<html>
  <head>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <title>Multi Page Example</title>
```

New terms and **important words** are shown in bold. Words that you see on the screen, in menus or dialog boxes for example, appear in the text like this: "Imagine our **Megacorp** page. It's got three pages, but the **Products** page is a separate HTML file."

 Warnings or important notes appear in a box like this.

 Tips and tricks appear like this.

Reader feedback

Feedback from our readers is always welcome. Let us know what you think about this book – what you liked or may have disliked. Reader feedback is important for us to develop titles that you really get the most out of.

To send us general feedback, simply send an e-mail to feedback@packtpub.com, and mention the book title through the subject of your message.

If there is a topic that you have expertise in and you are interested in either writing or contributing to a book, see our author guide on www.packtpub.com/authors.

Customer support

Now that you are the proud owner of a Packt book, we have a number of things to help you to get the most from your purchase.

Downloading the example code

This book contains many code samples. You are not expected to type them in. You should not type them all in. Rather, you should download them from the public Github repository setup for the book: <https://github.com/cfjedimaster/jQuery-Mobile-Book>. The Github repository will be updated as typos and other mistakes are found in the book. Therefore, it is possible the code may not match exactly the text in the book.

If you are not familiar with Github, then simply click the **Downloads** tab and then either **Download as zip** or **Download as tar.gz** to quickly get an archived collection of all the files.

You should extract these files onto a local web server. If you do not have one installed, we recommend installing Apache (<http://httpd.apache.org/>). Apache works on all platforms, is free, and is typically easy to install. Once extracted, you can edit these files, view them in your browser, or copy them as a starting point for your own projects.

You can also download the example code files for all Packt books you have purchased from your account at <http://www.packtpub.com>. If you purchased this book elsewhere, you can visit <http://www.packtpub.com/support> and register to have the files e-mailed directly to you.

Errata

Although we have taken every care to ensure the accuracy of our content, mistakes do happen. If you find a mistake in one of our books—maybe a mistake in the text or the code—we would be grateful if you would report this to us. By doing so, you can save other readers from frustration and help us improve subsequent versions of this book. If you find any errata, please report them by visiting <http://www.packtpub.com/support>, selecting your book, clicking on the **errata submission form** link, and entering the details of your errata. Once your errata are verified, your submission will be accepted and the errata will be uploaded to our website, or added to any list of existing errata, under the Errata section of that title.

Piracy

Piracy of copyright material on the Internet is an ongoing problem across all media. At Packt, we take the protection of our copyright and licenses very seriously. If you come across any illegal copies of our works, in any form, on the Internet, please provide us with the location address or website name immediately so that we can pursue a remedy.

Please contact us at copyright@packtpub.com with a link to the suspected pirated material.

We appreciate your help in protecting our authors, and our ability to bring you valuable content.

Questions

You can contact us at questions@packtpub.com if you are having a problem with any aspect of the book, and we will do our best to address it.

1

Preparing your First jQuery Mobile Project

You know what jQuery Mobile is, the history of it as well as its features and goals. Now we're actually going to build our first jQuery Mobile website (well, web page) and see how easy it is to use.

In this chapter we will:

- Create a simple HTML page
- Add jQuery Mobile to the page
- Make use of custom data attributes (data-*)
- Update the HTML to make use of the data attributes jQuery Mobile recognizes

Important preliminary points

You can find all the source code for this chapter in the c1 folder of the ZIP file you downloaded from Github. If you wish to type everything out by hand, we recommend you use similar file names.

Building an HTML page

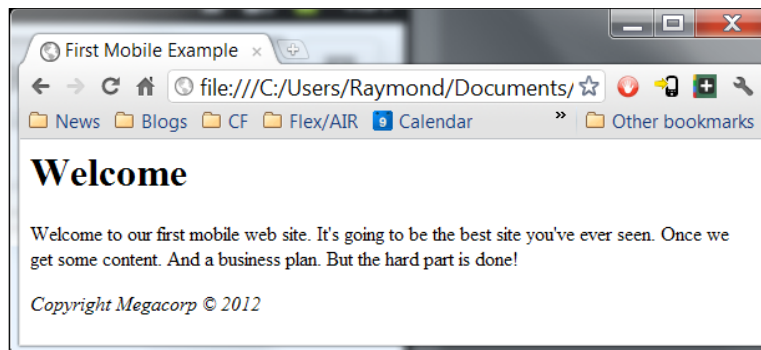

Let's begin with a simple web page that is not mobile optimized. To be clear, we aren't saying it can't be used on a mobile device. Not at all. But it may not be *usable* on a mobile device. It may be hard to read (text too small). It may be too wide. It may use forms that don't work well on a touch screen. We don't know what kinds of problems will have at all until we start testing. (And we've all done testing of our websites on mobile devices to see how well they work, right?)

Lets have a look at Listing 1-1:

Listing 1-1: test1.html

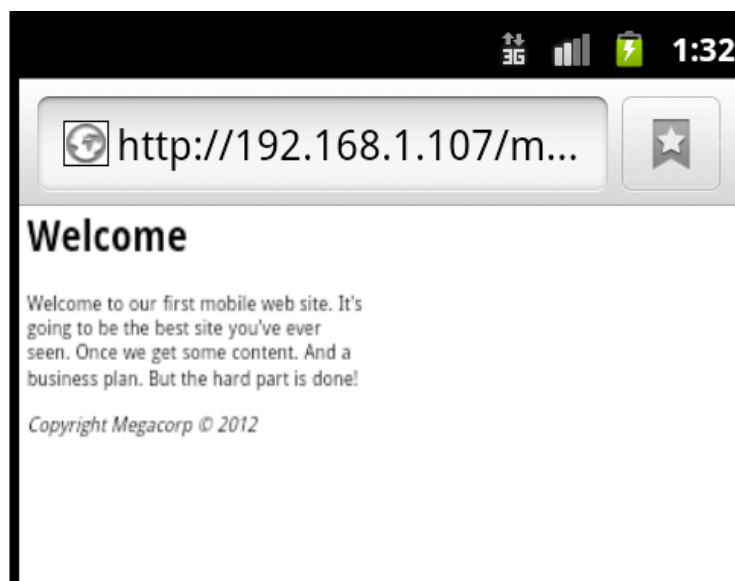

```
<html>
  <head>
    <title>First Mobile Example</title>
  </head>
  <body>
    <h1>Welcome</h1>
    <p>
      Welcome to our first mobile web site. It's going to be the
      best site you've ever seen. Once we get some content. And a
      business plan. But the hard part is done!
    </p>
    <p>
      <i>Copyright Megacorp &copy; 2012</i>
    </p>
  </body>
</html>
```

As we said, nothing too complex, right? Let's take a quick look at this in the browser:

[ You can also download the example code files for all Packt books you have purchased from your account at <http://www.packtpub.com>. If you purchased this book elsewhere, you can visit <http://www.packtpub.com/support> and register to have the files e-mailed directly to you.]

Not so bad, right? But let's take a look at the same page in a mobile simulator:

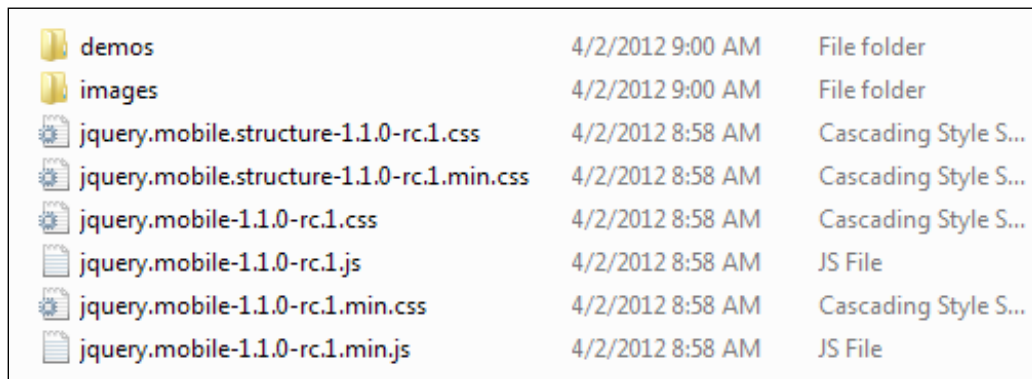

Wow, that's pretty tiny. You've probably seen web pages like this before on your mobile device. You can, of course, typically use pinch and zoom or double click actions to increase the size of the text. But it would be preferable to have the page render immediately in a mobile friendly view. This is where jQuery Mobile enters.

Getting jQuery Mobile

In the preface we talked about how jQuery Mobile is "just" a set of files. That isn't said to minimize the amount of work done to create those files, or how powerful they are, but to emphasize that using jQuery Mobile means you don't have to install any special tools or server. You can download the files and simply include them in your page. And if that's too much work, you have an even simpler solution. jQuery Mobile's files are hosted on a Content Delivery Network (CDN). This is a resource hosted by them and guaranteed (as much as anything like this can be) to be online and available. Multiple sites are already using these CDN hosted files. That means when your users hit your site they will already have the resources in their cache. For this book we will be making use of the CDN hosted files, but just for this first example we'll download and extract the bits. I recommend doing this anyway for those times when you're on an airplane and wanting to whip up a quick mobile site.

To grab the bits, visit <http://jquerymobile.com/download>. There are a few options here but you want the ZIP file option. Go ahead and download that ZIP file and extract it. (The ZIP file you downloaded earlier from Github has a copy already.) The following screenshot demonstrates what you should see after extracting the files from the ZIP file:

 demos	4/2/2012 9:00 AM	File folder
 images	4/2/2012 9:00 AM	File folder
 jquery.mobile.structure-1.1.0-rc.1.css	4/2/2012 8:58 AM	Cascading Style S...
 jquery.mobile.structure-1.1.0-rc.1.min.css	4/2/2012 8:58 AM	Cascading Style S...
 jquery.mobile-1.1.0-rc.1.css	4/2/2012 8:58 AM	Cascading Style S...
 jquery.mobile-1.1.0-rc.1.js	4/2/2012 8:58 AM	JS File
 jquery.mobile-1.1.0-rc.1.min.css	4/2/2012 8:58 AM	Cascading Style S...
 jquery.mobile-1.1.0-rc.1.min.js	4/2/2012 8:58 AM	JS File

Important note: At the time this book was written, jQuery Mobile was preparing for the release of Version 1.1. The released version was 1.0.1. But with 1.1 so close to release, that version is in use. Obviously, by the time you read this book a later version may be released. The file names you see listed in the previous screenshot are version specific, so keep in mind they may look a bit different for you.

Notice the ZIP file contains a CSS and JavaScript file for jQuery Mobile, as well as a minified version of both. You will typically want to use the minified version in your production apps and the regular version while developing. The images folder has 6 images used by the CSS when generating mobile optimized pages. So, to be clear, the entire framework, and all the features we will be talking about over the rest of the book, will consist of a framework of 8 files. Of course, you also need to include the jQuery library. You can download that separately at www.jquery.com.

Implementing jQuery Mobile

Ok, we've got the bits, how do we use them? Adding jQuery Mobile support to a site requires the following three steps at a minimum:

1. First add the HTML 5 doctype to the page: `<!DOCTYPE html>`. This is used to help inform the browser about the type of content it will be dealing with.

2. Add a viewport metatag: `<meta name="viewport" content="width=device-width, initial-scale=1">`. This helps set better defaults for pages when viewed on a mobile device.
3. Finally – the CSS, JavaScript library, and jQuery itself need to be included into the file.

Let's look at a modified version of our previous HTML file that adds all of the above:

Listing 1-2: test2.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>First Mobile Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="jquery.mobile-1.1.0-rc.1.css" />
    <script type="text/javascript"
      src="http://code.jquery.com/jquery-1.7.1.min.js"></script>
    <script type="text/javascript" src="jquery.mobile-1.1.0-
      rc.1.min.js"></script>
  </head>
  <body>
    <h1>Welcome</h1>
    <p>
      Welcome to our first mobile web site. It's going to be the best
      site you've ever seen. Once we get some content. And a business
      plan. But the hard part is done!
    </p>
    <p>
      <i>Copyright Megacorp &copy; 2012</i>
    </p>
  </body>
</html>
```

For the most part, this version is the exact same as listing 1, except for the addition of the doctype, the CSS link, and our two JavaScript libraries. Notice we point to the hosted version of the jQuery library. It's perfectly fine to mix local JavaScript files and remote ones. If you wanted to ensure you could work offline, you can simply download the jQuery library as well.

So while nothing changed in the code between the `body` tags, there is going to be a radically different view now in the browser. The following screenshot shows how the Android mobile browser renders the page now:

Right away you see a couple of differences. The biggest difference is the relative size of the text. Notice how much bigger it is and easier to read. As we said, the user could have zoomed in on the previous version, but many mobile users aren't aware of this technique. This page loads up immediately in a manner that is much more usable on a mobile device.

Working with data attributes

As we saw in the previous example, just adding in jQuery Mobile goes a long way to updating our page for mobile support. But there's a lot more involved to really prepare our pages for mobile devices. As we work with jQuery Mobile over the course of the book, we're going to use various data attributes to mark up our pages in a way that jQuery Mobile understands. But what are data attributes?

HTML5 introduced the concept of data attributes as a way to add ad-hoc values to the DOM (Document Object Model). As an example, this is a perfectly valid HTML:

```
<div id="mainDiv" data-ray="moo">Some content</div>
```

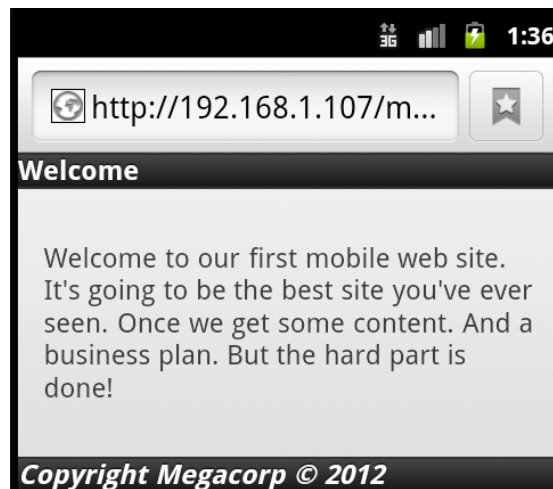

In the previous HTML, the `data-ray` attribute is completely made up. However, because our attribute begins with `data-`, it is also completely legal. So what happens when you view this in your browser? Nothing! The point of these data attributes is to integrate with other code, like JavaScript, that does... whatever it wants basically with them. So for example, you could write JavaScript that finds every item in the DOM with the `data-ray` attribute and change the background color to whatever was specified in the value.

This is where jQuery Mobile comes in, making extensive use of data attributes, both for markup (to create widgets) and behavior (to control what happens when links are clicked). Let's look at one of the main uses of data attributes within jQuery Mobile – defining pages, headers, content, and footers:

Listing 1-3: test3.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>First Mobile Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="jquery.mobile-1.1.0-rc.1.css" />
    <script type="text/javascript" src="http://code.jquery
      .com/jquery-1.7.1.min.js"></script>
    <script type="text/javascript" src="jquery.
      mobile-1.1.0-rc.1.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">Welcome</div>
      <div data-role="content">
        <p>
          Welcome to our first mobile web site. It's going to be the
            best site you've ever seen. Once we get some content. And
              a business plan. But the hard part is done!
        </p>
      </div>
      <div data-role="footer">
        <i>Copyright Megacorp &copy; 2012</i>
      </div>
    </div>
  </body>
</html>
```

Compare the previous code snippet to listing 1-2 and you can see that the main difference was the addition of the `div` blocks. One `div` block defines the page. Notice it wraps all of the content inside the `body` tags. Inside the `body` tag, there are three separate `div` blocks. One has a role of "header", another a role of "content", and the final one is marked as "footer". All the blocks use `data-role` which should give you a clue that we're defining a role for each of the blocks. As we stated above, these data attributes mean nothing to the browser itself. But let's look what at what jQuery Mobile does when it encounters these tags:

Notice right away that both the header and footer now have a black background applied to them. This makes them stick out even more from the rest of the content. Speaking of content, the page text now has a bit of space between it and the sides. All of this was automatic once the `div` tags with the recognized `data-roles` were applied. This is a theme you're going to see repeated again and again as we go through this book. A vast majority of the work you'll be doing will involve the use of data attributes.

Summary

In this chapter, we talked a bit about how web pages may not always render well in a mobile browser. We talked about how the simple use of jQuery Mobile can go a long way to improving the mobile experience for a website. Specifically, we discussed how you can download jQuery Mobile and add it to an existing HTML page, what data attributes mean in terms of HTML, and how jQuery Mobile makes use of data attributes to enhance your pages. In the next chapter, we will build upon this usage and start working with links and multiple pages of content.

2

Working with jQuery Mobile Pages

In the previous chapter, you saw how easy it was to add jQuery Mobile to a simple HTML page. While it would be nice if every website consisted of one, and only one page, real websites consist of multiple pages connected via links. jQuery Mobile makes it easy to work with multiple pages and provides many different ways to create, and link, to the pages.

In this chapter, we will:

- Add multiple pages to one jQuery Mobile file
- Discuss how links are modified by jQuery Mobile (and how to disable it)
- Demonstrate how additional files can be linked to and added to a jQuery Mobile site
- Discuss how jQuery Mobile automatically handles URLs to allow for easy bookmarking

Important preliminary points

As mentioned in the previous chapter, all of the code from this chapter is available via the ZIP file downloaded at Github.

Adding multiple pages to one file

In the previous chapter, we worked on a file that had a simple page of text. For our first modification, we're going to add another page to the file and create a link to it. If you remember, jQuery Mobile looks for a particular `<div>` wrapper to help it know where your page is: `<div data-role="page">`. What makes jQuery Mobile so simple to use is that we can add another page by simply adding another div using the same format. The following code snippet Listing 2-1 shows a simple example of this feature:

Listing 2-1: test1.html

```
<!DOCTYPE html>
<html>
  <head>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <title>Multi Page Example</title>
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="homePage">
      <div data-role="header">Welcome</div>
      <div data-role="content">
        <p>
          Welcome to our first mobile web site. It's going to be the
            best site you've ever seen. Once we get some content. And
            a business plan. But the hard part is done!
        </p>
        <p>
          You can also <a href="#aboutPage">learn more</a> about
            Megacorp.
        </p>
      </div>
      <div data-role="footer">
        <i>Copyright Megacorp &copy; 2012</i>
      </div>
    </div>
```

```
<div data-role="page" id="aboutPage">
  <div data-role="header">About Megacorp</div>
  <div data-role="content">
    <p>
      This text talks about Megacorp and how interesting it is.
      Most likely though you want to
      <a href="#homePage">return</a> to the home page.
    </p>
  </div>
  <div data-role="footer">
    <i>Copyright Megacorp &copy; 2012</i>
  </div>
</div>
</body>
</html>
```

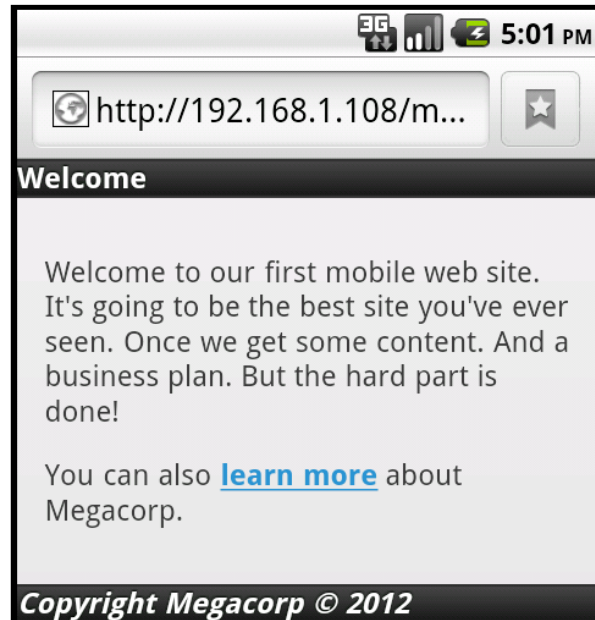

OK, so as always, we begin our template with a few required bits: the HTML5 doctype, the meta tag, one CSS include, and two JavaScript files. This was covered in the previous chapter and we will not be mentioning it again. Note that this template switches over to the CDN version of the CSS and JavaScript libraries:

```
<link rel="stylesheet" href="http://code.jquery.com/
  mobile/latest/jquery.mobile.min.css" />
<script src="http://code.jquery.com/jquery-1.7.1.min.js"></script>
<script src="http://code.jquery.com/mobile/latest/
  jquery.mobile.min.js"></script>
```

These versions are hosted by the jQuery team and have the benefit of always being the latest version. Most likely your visitors will have loaded these libraries already so they exist in their cache before arriving at your mobile site. While this is the route we will take going further with our examples, remember that you can always use the version you downloaded instead.

Notice now we have two `<div>` blocks. The first hasn't much changed from the previous example. We've added a unique ID (`homePage`), as well as a second paragraph. Notice the link in the second paragraph. It's using a standard internal link (`#aboutPage`) to tell the browser that we want to simply scroll the browser down to that part of the page. The target specified, `aboutPage`, is defined right below in another `div` block.

In a traditional web page, this would display as two main blocks of text on a page. Clicking any of the two links would simply scroll the browser up and down accordingly. However, jQuery Mobile is going to do something significantly different here. The following figure shows how the page is rendered in the mobile browser:

Notice something? Even though our HTML included two blocks of text (the two `<div>` blocks) it only rendered one. jQuery Mobile will always display the first page it finds, and only that page. Here comes the best part. If you click on the link, the second page automatically loads. Using your device's back button, or simply clicking the link, will return you back to the first page. You will also notice a smooth transition. This is something you can configure later on. But all of the interactions here, the showing and hiding of pages, the transitions, were all done automatically by jQuery Mobile. Now is a good time to talk about links and what jQuery Mobile does when you click on them.

jQuery Mobile, links, and you

When jQuery Mobile encounters a simple link (`Foo`), it will automatically capture any clicks on that link and change it to an Ajax-based load. This means that if it detects that the target is something on the same page, that is, the hashmark style (`href="#foo"`) links we used above, it will handle transitioning the user to a new page. If it detects a page to another file on the same server, it will use Ajax to load the page and replace the currently visible one.

If you link to an external site, then jQuery Mobile will leave the link as is and the normal link behavior will occur. There may be times when you want to disable jQuery Mobile from doing anything with your links at all. In that case, you can make use of a data attribute that lets the framework know it shouldn't do anything at all. An example:

```
<a href="foo.html" data-ajax="false">Normal, non-special link</a>
```

As we saw in *Chapter 1, Preparing Your First jQuery Mobile Project*, jQuery Mobile makes heavy use of data attributes. It is also very good at letting you disable behaviors you don't like. As we continue in the book you will see example after example of something jQuery Mobile does to enhance your site for mobile devices. In all of these cases though, the framework recognizes there may be times when you want to disable that.

Working with multiple files

In an ideal world, we could build an entire website with one file, never have to perform revisions, and be done with every project by 2 P.M. on Friday. But in the real world we have to deal with lots of files, lots of revisions, and, unfortunately, lots of work. In the earlier code listing you saw how we can include two pages within one file. jQuery Mobile handles this easily enough. But you can imagine that this would get unwieldy after a while. While we could include ten, twenty, even thirty pages, this is going to make the file difficult to work with and make the initial download for the user that much slower.

To work with multiple pages, and files, all we need to do is make a simple link to other files in the same domain as our first file. We can even combine the first technique (two pages in one file) with links to other files. In *listing 2-2*, we've modified the first example to add a link to a new page. Note that we keep the existing About page.

```
Listing 2-2:test2.html
<!DOCTYPE html>
<html>
  <head>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <title>Multi Page Example (2)</title>
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
```

```
</head>
<body>
  <div data-role="page" id="homePage">
    <div data-role="header">Welcome</div>
    <div data-role="content">
      <p>
        Welcome to our first mobile web site. It's going to be the
        best site you've ever seen. Once we get some content. And
        a business plan. But the hard part is done!
      </p>
      <p>
        Find out about our wonderful
        <a href="products.html">products</a>.
      </p>
      <p>
        You can also <a href="#aboutPage">learn more</a> about
        Megacorp.
      </p>
    </div>
    <div data-role="footer">
      <i>Copyright Megacorp &copy; 2012</i>
    </div>
  </div>
  <div data-role="page" id="aboutPage">
    <div data-role="header">About Megacorp</div>
    <div data-role="content">
      <p>
        This text talks about Megacorp and how interesting it is.
        Most likely though you want to
        <a href="#homePage">return</a> to the home page.
      </p>
    </div>
    <div data-role="footer">
      <i>Copyright Megacorp &copy; 2012</i>
    </div>
  </div>
</body>
</html>
```

Now, let's look at listing 2-3, our products page:

```
Listing 2-3: products.html
<!DOCTYPE html>
<html>
  <head>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <title>Products</title>
```

```

<link rel="stylesheet" href="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.css" />
<script src="http://code.jquery.com/jquery-
  1.7.1.min.js"></script>
<script src="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page" id="productsPage">
    <div data-role="header">Products</div>
    <div data-role="content">
      <p>
        Our products include:
      </p>
      <ul>
        <li>Alpha Series</li>
        <li>Beta Series</li>
        <li>Gamma Series</li>
      </ul>
    </div>
  </div>
</body>
</html>

```

Our products page is rather simple, but notice that we included the jQuery and jQuery Mobile resources on top. Why? I mentioned earlier that jQuery Mobile is going to use Ajax to load in your additional pages. If you open up `test2.html` in either Chrome or a Firebug-enabled Firefox you can see this for yourself. Clicking on the link for products will fire an XHR (think Ajax) request, as shown in the following role:

That's neat. But what happens when someone bookmarks the application? Let's now take a look at how jQuery Mobile handles URLs and navigation.

What is Firebug?

Firebug is an extension for Firefox (www.getfirebug.com) that provides a suite of developer-related tools for your browser. Chrome has similar tools built-in. These tools allow for a number of features, one of which is the ability to monitor XHR (or Ajax) related requests.

jQuery Mobile and URLs

If you've opened up `test2.html` in your browser and played with it, you may have noticed something interesting about the URLs as you navigate. Following is the initial URL. (The address and folder will, of course, differ on your computer):

`http://localhost/mobile/c2/test2.html`.

After clicking on products, the URL changes to `http://localhost/mobile/c2/products.html`. If I click back, and click **learn more**, I get `http://localhost/mobile/c2/test2.html#aboutPage`.

In both sub pages (the Products page and the About page) the URL was changed by the framework itself. The framework uses `history.pushState` and `history.replaceState` in browsers that support it. For older browsers, or browsers that don't support JavaScript manipulation of the URL, hash based navigation is used instead. The products link, when viewed in Internet Explorer, looks like the following:

`http://localhost/mobile/c2/test2.html#/mobile/c2/products.html`.

What's interesting is that in this bookmark style, `test2.html` is always loaded first. You could actually build your `products.html` to only include the div and be assured that if the request was made for products first, it would still render correctly. It's the newer, fancier browsers that have an issue. If you didn't include the proper jQuery and jQuery Mobile includes, when they go directly to `products.html` you would end up with a page that has no styles. It's best to simply always include your proper header files (the CSS, the JavaScript, and so on). Any decent editor will provide simple ways to create templates.

Additional customization

Working with multiple pages in jQuery Mobile is pretty simple. You could take what's been discussed in the first two chapters and build a pretty simple, but mobile compliant, website right now. The following are a few more interesting tricks you may want to consider.

Page titles

You may have noticed when you clicked on the **Products** page in the previous example, the title of the browser correctly updated to `Products`. This is because jQuery Mobile noticed, and parsed in, the title tag from the `products.html` file. But if you click on the **About** link, you don't get the same behavior. Obviously, since the **About** page resides within the same HTML, it has the same title tag as well. jQuery Mobile provides a simple way to solve this and once again it involves data tags. The following code snippet shows a simple way to add a title to embedded pages:

```
<div data-role="page" id="aboutPage" data-title="About Megacorp">
  <div data-role="header">About Megacorp</div>
  <div data-role="content">
    <p>
      This text talks about Megacorp and how interesting it is. Most
      likely though you want to
      <a href="#homePage">return</a> to the home page.
    </p>
  </div>
  <div data-role="footer">
    <i>Copyright Megacorp &copy; 2012</i>
  </div>
</div>
```

Notice the new `data-title` tag added to the `div` tag. jQuery Mobile will notice then and when the **About** page is loaded, it will update the browser title as well. Again, this is only required when you include multiple pages within one HTML file. You can find this version in `test3.html`:

Prefetching content

The benefit of including all your content within one HTML file is that all of your pages are available immediately. But the negatives (too difficult to update, too slow for an initial download) far outweigh that. Most jQuery Mobile applications will include multiple files and typically just one or two pages per file. You can, however, ensure speedier loading of some pages to help improve the user experience. Imagine our **Megacorp** page. It's got three pages, but the **Products** page is a separate HTML file. Since it's the only real content on the site, most likely all of our users will end up clicking that link. We can tell jQuery Mobile to prefetch the content immediately upon the main page loading. That way when the user does click the link, the page will load much quicker. Once again, this comes down to one simple data attribute.

```
<p>
  Find out about our wonderful <a href="products.html" data-
    prefetch>products</a>.
</p>
```

In the previous link, all we've done is added `data-prefetch` to the link. When jQuery Mobile finds this in a link it will automatically fetch the content right away. Now, when the user clicks the **Products** link, they will see the content even quicker. This modification was saved in `test4.html`.

Obviously, this technique should be used with care. Given a page with four main links, you may want to consider only prefetching the two most popular pages, not all four.

Changing page transitions

Earlier, we mentioned that you could configure the transitions jQuery Mobile uses between pages. Later in the book, we'll discuss how to do that globally, but if you want to switch to a different transition for a particular link, just include a `data-transition` attribute in your link:

```
<p>
  Find out about our wonderful <a href="products.html" data-
    transition="pop">products</a>.
</p>
```

Many transitions also support a reverse action. Normally jQuery Mobile figures out if you need this, but if you want to force a direction, use the `data-direction` attribute:

```
<p>
  Find out about our wonderful <a href="products.html" data-
    transition="pop" data-direction="reverse">products</a>.
</p>
```

Summary

This chapter further fleshed out the concept of jQuery Mobile pages and how to work with multiple pages. Specifically we saw how one physical file can contain many different pages. jQuery Mobile will handle hiding all but the first page. We also saw how you can link to other pages and how jQuery Mobile uses Ajax to dynamically load the content into the browser. Next we discussed how jQuery Mobile handles updating the URL of the browser in order to enable bookmarking. Finally, we discussed two utilities that will help to improve your page. The first way was to provide a title for embedded pages. The second technique demonstrated how to prefetch content to further improve the experience of the users visiting your site.

In the next chapter, we'll take a look at headers, footers, and navigation bars. These will greatly enhance our pages and make them easier to navigate.

3

Enhancing Pages with Headers, Footers, and Toolbars

Toolbars provide a simple way to add navigation elements to a mobile web site. They can be especially useful for consistent, or site-wide navigation controls that users can always refer to when navigating through your application.

In this chapter, we will:

- Talk about how to create both headers and footers
- Discuss how to turn these headers and footers into useful toolbars
- Demonstrate how to create fixed positioned toolbars that always show up, no matter how large the content of a particular page is
- Show an example of navigation bars

Important preliminary points

As mentioned in the previous chapter, all of the code from this chapter is available via the ZIP file downloaded at Github. Most of the code samples in this chapter are short, therefore the complete code should be used when testing.

Adding headers

You've already worked with headers before, so the code will be familiar. In this chapter, we will study them deeper and demonstrate how to add additional functionality, like buttons, to your site headers.

If you remember, a header can be defined by simply using a div with the appropriate role:

```
<div data-role="header">My Header</div>
```

The previous tag will add a nice black background to the text making it stand out a bit more, as shown in the following screenshot:

However, we can make this even nicer. By including an `h1` tag around our text, jQuery Mobile will make the header even larger, and automatically center the text, as shown in the screenshot following the tag:

```
<div data-role="header"><h1>My Header</h1></div>
```

Right away you can see the difference. We can further add functionality to headers by adding buttons. Buttons could be used for navigation (for example, to return to the home screen), or to provide links to related pages. Because the center of the header is used for text, there are only two *spaces* available for buttons – one to the left and one to the right. Buttons can be added simply by creating links in your header. The first link will be to the left of the text and the second link to the right. The following code snippet is an example:

```
<div data-role="header">
  <a href="index.html">Home</a>
  <h1>My Header</h1>
  <a href="contact.html">Contact</a>
</div>
```

When viewed in the mobile browser, you can see the following screenshot:

Notice how the simpler links were automatically turned into big buttons, making them easier to use and more "control like" for the header. You may be wondering, what if you only want one button, and want it on the right-hand side? Removing the first button and keeping the second in place will not work, as shown in the following code snippet:

```
<div data-role="header">
  <h1>My Header</h1>
  <a href="contact.html">Contact</a>
</div>
```

The previous code snippet creates a button in the header but on the left-hand side. In order to position the button to the right, simply add the class `ui-btn-right`. The following code snippet is an example:

```
<div data-role="header">
  <h1>My Header</h1>
  <a href="contact.html" class="ui-btn-right">Contact</a>
</div>
```

You can also specify `ui-btn-left` to place a link on the left-hand side, but as demonstrated in the previous code snippet, that's the normal behavior:

Icon sneak peak

While not specifically a header toolbar feature, one interesting feature available to all buttons in jQuery Mobile is the ability to specify an icon. A set of simple, easily recognizable icons ship with jQuery Mobile and are available to use immediately. These icons will be discussed further in *Chapter 6, Creating Mobile Optimized Forms*, but as a quick preview, the following code snippet shows a header with two customized icons:

```
<div data-role="header">
  <a href="index.html" data-icon="home">Home</a>
  <h1>My Header</h1>
  <a href="contact.html" data-icon="info">Contact</a>
</div>
```

Notice the new attribute, `data-icon`. When viewed in the browser, you get what is shown in the following screenshot:

Working with back buttons

Depending on your user's hardware, they may or may not have a physical back button. For devices that do, like Android phones, hitting the back button will work just fine in a jQuery Mobile application. Whatever page the user was on previously will be loaded as soon as the button is clicked. But on other devices, like the iPhone, there is no such button to click. While you can provide links to navigate around pages yourself, jQuery Mobile provides some nice built in support for navigating backwards out of the box.

There are two ways you can add an automatic back button. Listing 3-1 shows a simple, two page jQuery Mobile site. In the second page, we've added a new data attribute, `data-add-back-btn="true"`. This will create a back button in the header of the second page automatically. Next, we also added a simple link in the page content. While the actual URL for the link is blank, make note of the `data-rel="back"` attribute. jQuery Mobile will detect this link and automatically send the user to the previous page. The following code snippet is an example:

```
Listing 3-1: back_button_test.html
<!DOCTYPE html>
<html>
  <head>
    <title>Back Examples</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header"><h1>My Header</h1></div>
      <div data-role="content">
        <p>
          <a href="#subpage">Go to the sub page...</a>
        </p>
      </div>
    </div>
    <div data-role="page" id="subpage" data-add-back-btn="true">
      <div data-role="header"><h1>Sub Page</h1></div>
      <div data-role="content">
        <p>
          <a href="" data-rel="back">Go back...</a>
        </p>
      </div>
    </div>
  </body>
</html>
```

The following screenshot demonstrates the feature in action:

In case you're curious, the text of the button can be customized by simply using another data attribute in your page div: `data-add-back-btn="true" data-back-btn-text="Return"`. You can turn on back button support globally and change the text via JavaScript as well. This will be discussed in *Chapter 9, JavaScript Configuration and Utilities in jQuery Mobile*.

Working with footers

Footers are going to be, for the most part, much like headers. We've previously demonstrated the use of the data-role to create a footer:

```
<div data-role="footer">My Footer</div>
```

But, as with our headers, if we add the proper HTML inside the div tag, we can get even better formatting:

```
<div data-role="header"><h4>My Footer</h4></div>
```

With the addition of the `h4` tags, our footers are now centered and padded a bit to make them stand out more, as shown in the following screenshot:

As with headers, you can include buttons in the footer. Unlike headers, the buttons in a footer do not automatically position themselves to the left and right of the text. In fact, if you decide to make use of text and buttons, you want to ensure you remove the `h4` tag from the footer text or your footer will end up quite large. The following is a simple example with two buttons:

```
<div data-role="footer">
  <a href="credits.html">Credits</a>
  <a href="contact.html">Contact</a>
</div>
```

The following screen shot demonstrates this change:

This works – but notice the buttons don't have much space around them. You can improve that by adding a class called `ui-bar` to your footer `div` tag, as shown in the following code snippet:

```
<div data-role="footer" class="ui-bar">
  <a href="credits.html">Credits</a>
  <a href="contact.html">Contact</a>
</div>
```

Creating fixed and full screen headers and footers

In the previous discussion about headers and footers, you saw a few examples of how buttons can be added. These buttons could be useful for navigating in your site. But what if a particular page is somewhat long? A blog entry, for example, could be quite long, especially when viewed on a mobile device. As the user scrolls, the header, or footer, could be off screen. jQuery Mobile provides a way to create fixed position headers and footers. With this feature enabled, the header and footer will always be visible. They may disappear while the user scrolls, but as soon as they lift their finger and stop scrolling, the header and footer will reappear. This feature can be enabled by adding `data-position="fixed"` to the div tag used for either the header or footer. Listing 3-2 demonstrates an example. In order to ensure the page actually scrolls, many paragraphs of text were repeated. This has been removed from the code in the book, but exists in the actual file.

Listing 3-2: longpage.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Fixed Positioning Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header" data-position="fixed"><h1>My
        Header</h1></div>
      <div data-role="content">
        <p>
          Lorem ipsum dolor sit amet, consectetur adipiscing elit.
          Suspendisse id posuere lacus. Nulla ac sem ut eros
          dignissim interdum a et erat. Class aptent taciti
          sociosqu ad litora torquent per conubia nostra, per
          inceptos himenaeos. In ac tellus est. Nunc consequat
          metus lobortis enim mattis nec convallis tellus pulvinar.
          Nullam diam ligula, dictum sed congue nec, dapibus id
          ipsum. Ut facilisis pretium dui, nec varius dui iaculis
          ultricies. Maecenas sollicitudin urna felis, non faucibus
```

```

        leo. Cum sociis natoque penatibus et magnis dis
        parturient montes, nascetur ridiculus mus. In id volutpat
        lectus.Quisque mauris ipsum, vehicula id ornare aliquet,
        auctor volutpat dui. Sed euismod sem in arcu dapibus
        condimentum dictum nibh consequat.
    </p>
</div>
<div data-role="footer" data-position="fixed"><h4>My
    Footer</h4></div>
</div>
</body>
</html>

```

We won't bother with a screenshot of this example as it won't exactly convey the feature well, but if you try this in your mobile device, notice while scrolling up and down, as soon as you lift your finger the header and footer will both pop in. This gives the user access to them no matter how large the page may be.

Full screen positioning

Another option to consider is what's called full screen positioning. This is a metaphor commonly used with pictures, but can also be used where fixed positioned headers and footers are used. In this scenario, the header and footer appear and disappear with clicks. So, with a photo, this allows you a view of the photo as it is, but also the ability to get the header and footer back with a simple click. Perhaps, instead of full screen positioning you can consider it as *retrievable* headers and footers instead. In general, this is best used when you want the content of the page to be viewed by itself, again, an excellent example of this would be pictures.

To enable this feature, simply add `data-fullscreen="true"` to the div tag used to define the page. Listing 3-3 demonstrates this feature, as shown in the following code snippet:

Listing 3-3: fullscreen.html

```

<!DOCTYPE html>
<html>
  <head>
    <title>Full Screen Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>

```

```
</head>
<body>
  <div data-role="page" data-fullscreen="true">
    <div data-role="header" data-position="fixed"><h1>My
      Header</h1></div>
    <div data-role="content">
      <p>
        
      </p>
      <p>
      </p>
    </div>
    <div data-role="footer" data-position="fixed"><h4>My
      Footer</h4></div>
    </div>
  </body>
</html>
```

As with the previous example, the previous code snippet doesn't translate very well to static screen shots. Open it up in your mobile browser and take a look. Remember, you can click multiple times to toggle on and off the effect.

Working with navigation bars

You've seen a few examples now which include buttons with headers and footers, but jQuery Mobile has a cleaner version of this called NavBars (or navigation bars). These are full screen-wide bars used to hold buttons. jQuery Mobile also supports highlighting one button at a time as an active button. When used for navigation, this is an easy way to mark a page as being active.

A NavBar is simply an unordered list wrapped in a div tag that uses `data-role="navbar"`. Placed inside a footer it looks similar to the following code snippet:

```
<div data-role="footer">
  <div data-role="navbar">
    <ul>
      <li><a href="persistent_footer_index.html" class="ui-btn-
        active">Home</a></li>
      <li><a href="persistent_footer_credits.html" >Credits</a></li>
      <li><a href="persistent_footer_contact.html" >Contact</a></li>
    </ul>
  </div>
</div>
```

Notice the use of `class="ui-btn-active"` on the first link. This will mark the first button as active. jQuery Mobile won't be able to do this for you automatically, so as you build each page and make use of `navbar`, you will have to *move* the class appropriately. The following screenshot shows how it looks:

You can add up to 5 buttons and jQuery Mobile will appropriately size the buttons to make them fit. If you go over five, then the buttons will simply be split over multiple lines. Most likely this is not something you want to cover. Overwhelming the user with too many buttons is a sure way to confuse, and ultimately anger, your users.

You can also include a navbar in your header. If placed after the text, or any other buttons, jQuery Mobile will automatically drop it to the next line:

```
<div data-role="header">
  <h1>Home</h1>
  <div data-role="navbar">
    <ul>
      <li><a href="persistent_footer_index.html" class="ui-btn-active">Home</a></li>
      <li><a href="persistent_footer_credits.html" >Credits</a></li>
      <li><a href="persistent_footer_contact.html" >Contact</a></li>
    </ul>
  </div>
</div>
```

You can see an example of both of these in action in the file named `header_and_footer_with_navbar.html`.

Persisting navigation bar footers across multiple pages

Let's now take two of the previous topics and combine them into one incredibly cool little feature – multiple page persistent footers. It's a bit more work, but you can create a footer NavBar that will not disappear when switching from page to page. In order to do this, you have to follow a few simple rules:

- Your footer div must be present on all pages
- Your footer div must use the same `data-id` value across all pages
- You must use two CSS classes: `ui-state-persist` and `ui-btn-active`, on the *active* page in the NavBar
- You must also use the persistent footer feature

That sounded a bit complex, but it's really just a tiny bit more HTML in your template. In `listing 3-4`, an index page for a fictional company makes use of a footer NavBar. Note the use of `ui-state-persist` and `ui-btn-active` for the currently selected page.

Listing 3-4: `persistent_footer_index.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Persistent Footer Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header"><h1>Home</h1></div>
      <div data-role="content">
        <p>
          This is the Home Page
        </p>
```

```
</div>
<div data-role="footer" data-position="fixed" data-
  id="footernav">
  <div data-role="navbar">
    <ul>
      <li><a href="persistent_footer_index.html" class="ui-btn-
        active ui-state-persist">Home</a></li>
      <li><a href="persistent_footer_credits.html">
        Credits</a></li>
      <li><a href="persistent_footer_contact.html">
        Contact</a></li>
    </ul>
  </div>
</div>
</body>
</html>
```

The following screenshot shows how the complete page looks:

We don't need to worry so much about the other two pages. You can find them in the ZIP file you downloaded. The following code snippet is the footer section from the second page. Notice that the only change here is the movement of the `ui-btn-active` class:

```
<div data-role="footer" data-position="fixed" data-id="footernav">
  <div data-role="navbar">
    <ul>
      <li><a href="persistent_footer_index.html">Home</a></li>
      <li><a href="persistent_footer_credits.html" class="ui-btn-
        active ui-state-persist">Credits</a></li>
      <li><a href="persistent_footer_contact.html">Contact</a></li>
    </ul>
  </div>
</div>
```

Clicking from one page to another shows a smooth transition to each page, but the footer bar remains. Much like a framed site (don't shudder – frames weren't always looked at with scorn), the footer will stay as the user navigates throughout the site.

Summary

In this chapter, we discussed how to add headers, footers, and navigation bars (NavBars) to your jQuery Mobile pages. We showed how the proper div tags will create nicely formatted headers and footers on your page and how to make these headers and footers persist over a long page. Further, we demonstrated *full screen mode* for headers and footers. These are headers and footers that appear and disappear with clicks – perfect for images and other items you want to show in a full screen type view on your mobile device. Finally, we saw how to combine persistent footers and NavBars to create a footer that doesn't go away when the page changes.

In the next chapter, we'll do a deep dive into lists. Lists are one of the primary ways folks add navigation and menus to their mobile sites. jQuery Mobile provides a plethora of options for creating and styling lists.

4

Working with Lists

Lists are a great way to provide menus to users on a mobile website. jQuery Mobile provides a wealth of list options, from simple lists to lists with custom thumbnails and multiple user actions.

In this chapter, we will:

- Talk about how to create lists
- How to create linked and sub-menu style lists
- How to create different styles of lists

Creating lists

As you've (hopefully!) come to learn jQuery Mobile takes an approach of *enhancement* when it comes to UI. You take ordinary, simple HTML, add a bit of markup (sometimes!), and jQuery Mobile will do the heavy lifting of enhancing the UI. The same process applies to lists. We've all worked with simple lists in HTML before, the following code snippet is an example:

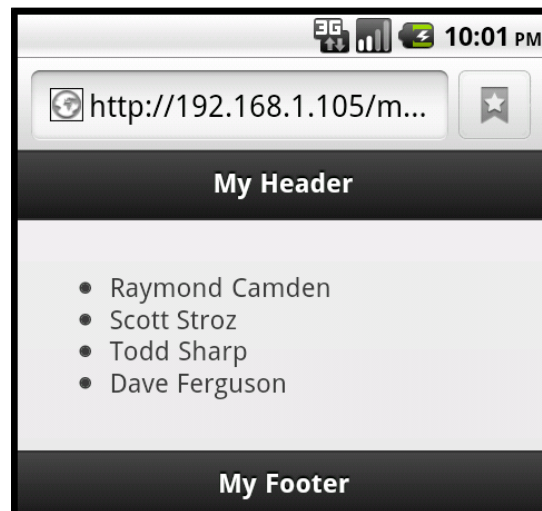

```
<ul>
  <li>Raymond Camden</li>
  <li>Scott Stroz</li>
  <li>Todd Sharp</li>
  <li>Dave Ferguson</li>
</ul>
```

And we all know how they are displayed (a bulleted list in the case of the previous code snippet). Let's take that list and drop it in a simple jQuery Mobile optimized page. Listing 4-1 takes a typical page and drops in our list:

Listing 4-1: test1.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Unordered List Example</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>My Header</h1>
      </div>
      <div data-role="content">
        <ul>
          <li>Raymond Camden</li>
          <li>Scott Stroz</li>
          <li>Todd Sharp</li>
          <li>Dave Ferguson</li>
        </ul>
      </div>
      <div data-role="footer">
        <h1>My Footer</h1>
      </div>
    </div>
  </body>
</html>
```

Given this HTML, jQuery Mobile gives us something nice right away, as shown in the following screenshot:

We can enhance that list though with a simple change. Take the ordinary `` tag from listing 4-1, and add a `data-role="listview"` attribute, as shown in the following line of code:

```
<ul data-role="listview">
```

In the code you download from Github, you can find this modification in `test2.html`. The change, though, is rather dramatic, as shown in the following screenshot:

You can see that the items no longer have the bullets in front, but they are much larger and easier to read. Things get even more interesting when we begin to add links to our list. In the following code snippet I've added a link to each list item:

```
<ul data-role="listview">
  <li><a href="ray.html">Raymond Camden</a></li>
  <li><a href="scott.html">Scott Stroz</a></li>
  <li><a href="todd.html">Todd Sharp</a></li>
  <li><a href="dave.html">Dave Ferguson</a></li>
</ul>
```

Once again you can find the complete file this was taken from in the ZIP file you downloaded earlier. This one may be found in `test3.html`. The following screenshot shows how this code is rendered:

Notice the new arrow image. This was automatically added when jQuery Mobile detected a link in your list. Now you've turned a relatively simple HTML unordered list into a simple menu system. This, by itself, is pretty impressive, but as we will see throughout the remaining chapter, jQuery Mobile provides a wealth of rendering options to let you customize your lists.

You may wonder how complex a menu system you can create. Because HTML itself supports nested lists, jQuery Mobile will also render them as well. Listing 4-2 demonstrates an example of a nested list:

```
Listing 4-2: Nested List
<!DOCTYPE html>
<html>
```

```
<head>
  <title>List Example</title>
  <meta name="viewport" content="width=device-width, initial-
    scale=1">
  <link rel="stylesheet" href="http://code.jquery.com/mobile/
    latest/jquery.mobile.min.css" />
  <script src="http://code.jquery.com/jquery-
    1.7.1.min.js"></script>
  <script src="http://code.jquery.com/mobile/
    latest/jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page">
    <div data-role="header">
      <h1>My Header</h1>
    </div>
    <div data-role="content">
      <ul data-role="listview">
        <li>Games
          <ul>
            <li>Pong</li>
            <li>Breakout</li>
            <li>Tron</li>
          </ul>
        </li>
        <li>Weapons
          <ul>
            <li>Nukes</li>
            <li>Swords</li>
            <li>Ninja Stars</li>
          </ul>
        </li>
        <li>Planets
          <ul>
            <li>Earth</li>
            <li>Jupiter</li>
            <li>Uranus</li>
          </ul>
        </li>
      </ul>
    </div>
    <div data-role="footer">
      <h1>My Footer</h1>
    </div>
  </div>
</body>
</html>
```

The HTML used in the nested lists, in the previous example aren't special in any way. It's standard. But jQuery Mobile will take the inner lists and actually hide the content. Even without links in the *upper* level LI items, they become links:

My Header	
Games	➤
Weapons	➤
Planets	➤
My Footer	

Clicking on one of the menu items loads the inner menu. If you run this in your own mobile device (or in your browser), notice the URL changes too, they create a bookmarkable view into the application:

Games
Pong
Breakout
Tron

Working with list feature

jQuery Mobile provides multiple different styles of lists, as well as different features that can be applied to them. For the next part of this chapter we'll cover some of these options available. These aren't in any particular order and are presented as a gallery of options available to you. You probably will not (and should not!) try to use all of these within one application, but it's good to keep in mind the various types of list styles jQuery Mobile has available.

Creating Inset lists

One of the simplest, and slickest changes you can make to your lists is to turn them into **Inset lists**. These are lists that do not take up the full width of the device. Taking the initial list we modified with `data-role="content"`, we can simply add another attribute, `data-inset="true"`, for the following code block (found in `test5.html`):

```
<ul data-role="listview" data-inset="true">
  <li>Raymond Camden</li>
  <li>Scott Stroz</li>
  <li>Todd Sharp</li>
  <li>Dave Ferguson</li>
</ul>
```

The result is now very different from the earlier example:

Creating list dividers

Another interesting UI element you may wish to add to your lists are dividers. These are a great way to separate a long list into something that is a bit easier to scan. Adding a list divider is as simple as adding a `li` tag that makes use of `data-role="list-divider"`. The following code snippet shows a simple example of this element:

```
<ul data-role="listview" data-inset="true">
  <li data-role="list-divider">Active</li>
  <li>Raymond Camden</li>
  <li>Scott Stroz</li>
  <li>Todd Sharp</li>
  <li data-role="list-divider">Archived</li>
  <li>Dave Ferguson</li>
</ul>
```

In the previous code block, note the two new `li` tags making use of the `list-divider` role. In this example, I've used these to separate the list of people into two groups. You can find the complete template in `test6.html`. The following screenshot shows how this is rendered:

Creating lists with count bubbles

Yet another interesting UI trick you can perform with jQuery Mobile lists are *count bubbles*. This is a UI enhancement that adds a simple number to the end of each list item. The numbers are wrapped in a *bubble* like look which is commonly used for e-mail-style interfaces. In the following code snippet, the count bubble is used to signify the number of cookies consumed at a technical conference:

```
<ul data-role="listview" data-inset="true">
  <li data-role="list-divider">Cookies Eaten</li>
  <li>Raymond Camden <span class="ui-li-count">9</span></li>
  <li>Scott Stroz <span class="ui-li-count">4</span></li>
  <li>Todd Sharp <span class="ui-li-count">13</span></li>
  <li>Dave Ferguson <span class="ui-li-count">8</span></li>
</ul>
```

In the previous code snippet, we make use of a `span` tag with a class of `ui-li-count` to wrap the numbers representing the amount of cookies eaten by each person. A simple HTML change, but consider how nicely it gets rendered, as shown in the following screenshot:

You can find a complete example of this feature in `test7.html`.

Using thumbnails and icons

Another common need with lists is to include images. jQuery Mobile supports both thumbnails (smallish images) and icons (even smaller images) that display well within the list control. Let's first look at including thumbnails within your list. Assuming you already have nicely sized images (our examples are all 160 pixels wide by 160 pixels high), you can simply include them within each `li` element as demonstrated in the following code snippet:

```
<ul data-role="listview" data-inset="true">
  <li><a href="ray.html"> Raymond Camden</a></li>
  <li><a href="scott.html"> Scott Stroz</a></li>
  <li><a href="todd.html"> Todd Sharp</a></li>
  <li><a href="dave.html"> Dave Ferguson</a></li>
</ul>
```

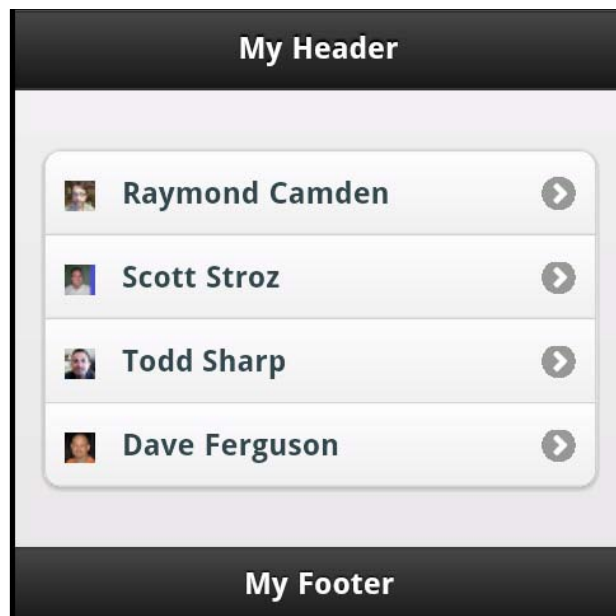

Nothing special is done with the image, no data attribute or class is added. jQuery Mobile will automatically left align the image and place the item text aligned to the top of each `li` block:

You can find the previous demonstration in `test8.html`. So what about icons? To include an icon in your code, add the class `ui-li-icon` to your image. (Note that the beginning of the class is `ui`, not `ul`.) The following code snippet is an example of that with our same list:

```
<ul data-role="listview" data-inset="true">
  <li><a href="ray.html">
    Raymond Camden</a></li>
  <li><a href="scott.html"> Scott Stroz</a></li>
  <li><a href="todd.html"> Todd Sharp</a></li>
  <li><a href="dave.html"> Dave Ferguson</a></li>
</ul>
```

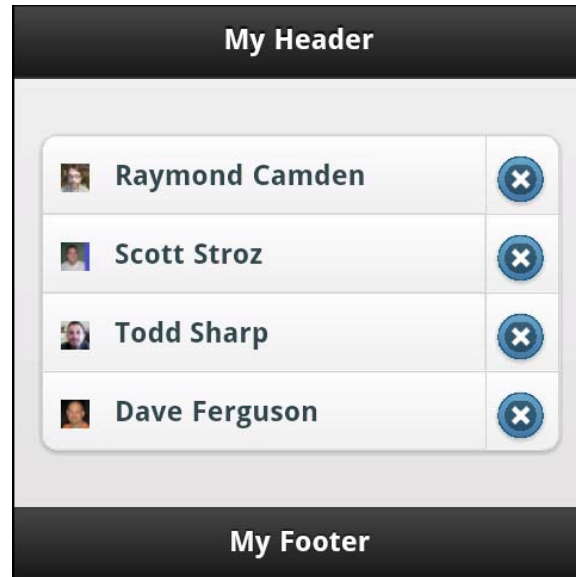

jQuery Mobile does shrink images when used with this class, but in my experience, the formatting was better when the image was resized beforehand. Doing so also improves the speed of your web page as the smaller images should result in quicker download times. The images above are all 16 pixels wide and high each. And the result is...

You can find the previous example in `test9.html`.

Creating Split Button lists

Another interesting feature of jQuery Mobile lists is the Split Button list. This is simply a list with multiple actions. There's a main action activated when the user clicks on the list item and a secondary action available via a button at the end of the list item. For this example, let's start with the screenshot first and then show how it's done:

As you can see, each list item has a secondary icon at the end of the row. This is an example of a split item list and is defined by simply adding a second link to a list item. For example:

```
<ul data-role="listview" data-inset="true">
  <li><a href="ray.html">
    Raymond Camden</a><a href="foo.html">Delete</a></li>
  <li><a href="scott.html"> Scott Stroz</a><a href="foo.html">Delete</a></li>
  <li><a href="todd.html"> Todd Sharp</a><a href="foo.html">Delete</a></li>
  <li><a href="dave.html"> Dave Ferguson</a><a href="foo.html">Delete</a></li>
</ul>
```

Note that the second link's text, **Delete**, is actually replaced by the icon. You can specify an icon by adding the data attribute `split-icon` to your `ul` tag, as shown in the following line of code:

```
<ul data-role="listview" data-inset="true" data-split-icon="delete">
```

The complete code for this example may be found in `test10.html`.

Using a search filter

For our last and final list feature we will look at search filters. The lists we've worked with so far have been pretty short. Longer lists though may make it difficult for users to find what they are looking for. jQuery Mobile provides an incredibly simple way to add a search filter to your lists. By adding `data-filter="true"` to any list, jQuery Mobile will automatically add a search field on top that filters as you type:

```
<ul data-role="listview" data-inset="true" data-filter="true">
  <li><a href="ray.html">Raymond Camden</a></li>
  <li><a href="scott.html">Scott Stroz</a></li>
  <li><a href="todd.html">Todd Sharp</a></li>
  <li><a href="dave.html">Dave Ferguson</a></li>
  (lots of items...)
</ul>
```

The result looks similar to the following screenshot:

If you begin typing in the previous field, the list automatically filters out the results as you type:

By default, the search is case-insensitive and matches anywhere in the list item. You can specify placeholder text for the search form by using `data-placeholder-text="Something"` in your `ul` tag. You can also specify a specific theme for the form using `data-filter-theme`. Finally, you can use JavaScript to add your own custom list filtering logic on a case by case basis.

Summary

This chapter discussed how to work with list views in jQuery Mobile. We saw how to turn a regular HTML list into a mobile optimized list and we demonstrated the numerous types of list features available with the framework.

In the next chapter, we'll take what we've learned already and build a real (albeit a bit simple) mobile-optimized website for a hotel.

5

Getting Practical – Building a Simple Hotel Mobile Site

In the past four chapters, we've looked at a few features of jQuery Mobile, but we already have enough knowledge to build a simple, pretty basic mobile-optimized website.

In this chapter, we will:

- Discuss what our hotel mobile website will contain
- Create the hotel mobile website using jQuery Mobile
- Discuss what could be done to make the site more interactive

Welcome to Hotel Camden

The Hotel Camden, known throughout the world, has had a web presence for some time now. (Ok, just to be clear, we're making this up!) They were an early innovator in the online world, beginning with a simple website in 1996 and gradually improving their online presence over the years. Online visitors to the Hotel Camden can now see virtual tours of rooms, check the grounds with a stunning 3D Adobe Flash plugin, and actually make reservations online. Recently, though, the owners of Hotel Camden have decided they want to move into the mobile space. For now, they want to start simply and create a mobile-optimized site which includes the following features:

- **Contact Information:** This will include both a phone number and an e-mail address. Ideally, the user will be able to click these and get connected to a real person.

- **Map of the hotel location:** This should include the address and possibly a map too.
- **Room types available:** This can be a simple list of the rooms from the simplest to the most grand.
- And finally – provide a way for the user to get to the real website. We are accepting that our mobile version will be somewhat limited (for this version), so at a minimum we should provide a way for users to return to the desktop version of the site.

The home page

Let's begin with the initial home page for the Camden Hotel. This will provide a simple list of options, as well as a bit of marketing text on the top. The text doesn't actually help anyone but the marketing staff won't let us release the site without it:

Listing 5-1: index.html

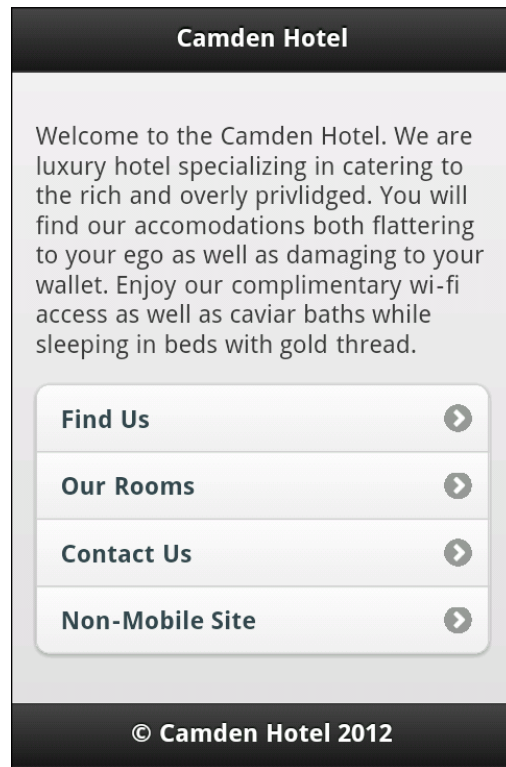

```
<!DOCTYPE html>
<html>
  <head>
    <title>The Camden Hotel</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Camden Hotel</h1>
      </div>
      <div data-role="content">
```

```
<p>
  Welcome to the Camden Hotel. We are a luxury hotel
  specializing in catering to the rich and overly
  privileged. You will find our accommodations both
  flattering to your ego, as well as damaging to your
  wallet. Enjoy our complimentary wi-fi access, as well as
  caviar baths while sleeping in beds with gold thread.
</p>
<ul data-role="listview" data-inset="true">
  <li><a href="find.html">Find Us</a></li>
  <li><a href="rooms.html">Our Rooms</a></li>
  <li><a href="contact.html">Contact Us</a></li>
  <li><a href="">Non-Mobile Site</a></li>
</ul>
</div>
<div data-role="footer">
  <h4>&copy; Camden Hotel 2012</h4>
</div>
</div>
</body>
</html>
```

At a high level, the code in `listing 5-1` is simply another instance of the jQuery page model we've discussed before. You can see what the CSS and JavaScript includes, as well as the div wrappers that set up our page, header, footer, and the content. Within our content div you can also see a list being used. We've left the URL blank for the Non-Mobile site option ("Non-Mobile Site") as we don't have a real website for the Camden Hotel.

The order of the list items is also thought out. Each item is listed in order of what the staff feel are the most common requests, with the number one being simply finding the hotel and the last option (ignoring leaving the site) being able to contact the hotel.

Over all – the idea of this example is to provide quick access to the most important aspects of what we think the hotel customers will need. The following screenshot shows how the site looks:

It isn't terribly sexy, but it renders well and is pretty easy to use. Later on you'll learn how to theme jQuery Mobile so your site doesn't look like every other example out there.

Finding the hotel

The next page of our mobile website is focused on helping the user find the hotel. This will include the address, as well as a map. Listing 5-2 shows how this is done:

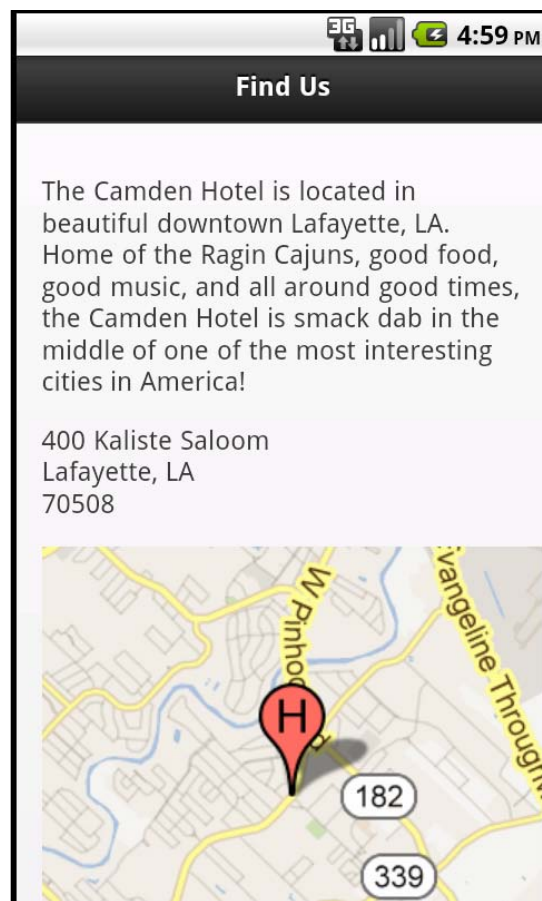

```
Listing 5-2: find.html
<!DOCTYPE html>
<html>
  <head>
    <title>The Camden Hotel - Find Us</title>
```

```

<meta name="viewport" content="width=device-width, initial-
scale=1">
<link rel="stylesheet" href="http://code.jquery.com/mobile/
latest/jquery.mobile.min.css" />
<script src="http://code.jquery.com/jquery-
1.7.1.min.js"></script>
<script src="http://code.jquery.com/mobile/latest/
jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page">
    <div data-role="header">
      <h1>Find Us</h1>
    </div>
    <div data-role="content">
      <p>
        The Camden Hotel is located in beautiful downtown
        Lafayette, LA. Home of the Ragin Cajuns, good food, good
        music, and all around good times, the Camden Hotel is
        smack dab in the middle of one of the most interesting
        cities in America!
      </p>
      <p>
        400 Kaliste Saloom<br/>
        Lafayette, LA<br/>
        70508
      </p>
      <p>
        
      </p>
    </div>
    <div data-role="footer">
      <h4>&copy; Camden Hotel 2012</h4>
    </div>
  </div>
</body>
</html>

```

The beginning of the template has our boiler plate included again, and as before, we have some marketing speak fluff on top. Immediately below this though is the address and the map. We created the map using one of the cooler Google features, Static Maps. You can read more about Google Static Maps at its home page: <http://code.google.com/apis/maps/documentation/staticmaps/>. Essentially, it is a way to create static maps via URL parameters. There's no zooming or panning in these maps, but if you are just trying to show a user where your business is located, it's an incredibly powerful and simple way to do so. While there are a large number of options you can use with this API, our example simply centers it on an address and adds a marker there as well. The label **H** is used for the marker, but a custom icon could be used instead. The following screenshot shows how this looks:

You could play around with that map URL a bit more to change the zoom, change the colors, and so on to your liking.

Listing the hotel rooms

Now let's look at `rooms.html`. This is where we will list out the room types available at the hotel:

Listing 5-3: `rooms.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>The Camden Hotel - Our Rooms</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Our Rooms</h1>
      </div>
      <div data-role="content">
        <p>
          Select a room below to see a picture.
        </p>
        <ul data-role="listview" data-inset="true">
          <li><a href="room_poor.html">Simple Elegance</a></li>
          <li><a href="room_medium.html">Gold Standard</a></li>
          <li><a href="room_high.html">Emperor Suite</a></li>
        </ul>
      </div>
      <div data-role="footer">
        <h4>&copy; Camden Hotel 2012</h4>
      </div>
    </div>
  </body>
</html>
```

The rooms page is simply a list of their rooms. The hotel has three levels of rooms, each linked to from the list, so the user can get details. You can find all three files in the ZIP downloaded from Github, but let's look at one of them in detail:

Listing 5-4: room_high.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>The Camden Hotel - Emperor Suite</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" data-fullscreen="true">
      <div data-role="header" data-position="fixed">
        <h1>Emperor Suite</h1>
      </div>
      <div data-role="content">
        
      </div>
      <div data-role="footer" data-position="fixed">
        <h4>&copy; Camden Hotel 2012</h4>
      </div>
    </div>
  </body>
</html>
```

The room detail page is only an image. Not very helpful, but it gets the point across. However, notice that we use a trick we learned in *Chapter 3, Enhancing Pages with Toolbars* – full screen mode. This allows the user to quickly click and hide the headers so they can see the room in all its glory:

Contacting the hotel

Now let's take a look at the contact page. This will provide the user with information on how to reach the hotel:

Listing 5-5: contact.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>The Camden Hotel - Contact</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Contact Us</h1>
      </div>
      <div data-role="content">
        <p>
          <b>Phone:</b> <a href="tel:555-555-5555">
            555-555-5555</a><br/>
          <b>Email:</b> <a href="mailto:people@camdenhotel.fake">
            people@camdenhotel.fake</a>
        </p>
      </div>
      <div data-role="footer">
        <h4>&copy; Camden Hotel 2012</h4>
      </div>
    </div>
  </body>
</html>
```

As before, we've wrapped our page in the proper script blocks and `div` tags. Make a special note of our two links. Both the phone and e-mail links use URLs that may not look familiar to you. The first, `tel:555-555-555`, is actually a way to ask the mobile device to call a phone number. Clicking it brings up the dialer, as shown in the following screenshot:

This makes it easy for the user to quickly call the hotel. Similarly the `mailto` link will allow for quickly jotting an email off to the hotel. Other URL schemes exist, including ones to send an SMS message. As you can probably guess, this scheme uses the form `"sms"`, so to begin an SMS message to a phone number, you could use the following URL: `sms://5551112222`.

Summary

In this chapter, we took what we've learned so far and built a very simple, but effective, website for a fake hotel. This website shared essential information for folks needing to learn about the hotel while on a mobile device, made use of Google's Static Maps API to create a simple map showing the hotel's location, and demonstrates the use of `tel` and `mailto` URL schemes for automatic phone dialing and e-mailing.

In the next chapter, we'll take a look at forms and how they are automatically improved with jQuery Mobile.

6

Working with Forms and jQuery Mobile

In this chapter, we will look at forms. Forms are a critical part of most websites as they provide the primary way for users to interact with the website. jQuery Mobile goes a long way to making forms both usable and elegantly designed for mobile devices.

In this chapter, we will:

- Talk about what jQuery Mobile does with forms
- Work with a sample form and describe how the results are handled
- Discuss specifics about how to build certain types of forms and make use of jQuery Mobile conventions

Before you begin

In this chapter, we're going to talk about forms and how jQuery Mobile enhances them. As part of our discussion, we will be posting our forms to the server. In order to have the server actually do something with the response we're going to make use of an application server from Adobe called ColdFusion. ColdFusion is not free for production use, but is 100% free for development and is a great server for building web applications. You do not need to download ColdFusion. If you do not, the forms you use within this chapter should not be submitted. This chapter does talk about how forms are submitted, but the response to the forms isn't really critical. If you know another language, like PHP, you should be able to simply mimic the code ColdFusion is using to echo back the form data.

ColdFusion (currently version 9) can be downloaded at <http://www.adobe.com/go/coldfusion>. Versions exist for Windows, OS X, and Linux. As stated above, you can run ColdFusion for free on your development server with no timeout restrictions.

What jQuery Mobile does with forms

Before we get into the code, there are two very important things you should know about what jQuery Mobile will do with your HTML forms:

- All forms will submit their data via Ajax. That means the data is sent directly to the action of your form and the result will be brought back to the user and placed within the page that held the form. This prevents a full page reload.
- All form fields are automatically enhanced, each in their own way. As we go on in the chapter you will see examples of this, but basically jQuery Mobile modifies your form fields to work better on a mobile device. A great example of this are buttons. jQuery Mobile automatically widens and heightens buttons to make them easier to click in the small form factor of a phone. If for some reason you don't like this, jQuery Mobile provides a way to disable this, either on a global or per use basis.

With that in mind, let's look at our first example in Listing 6-1:

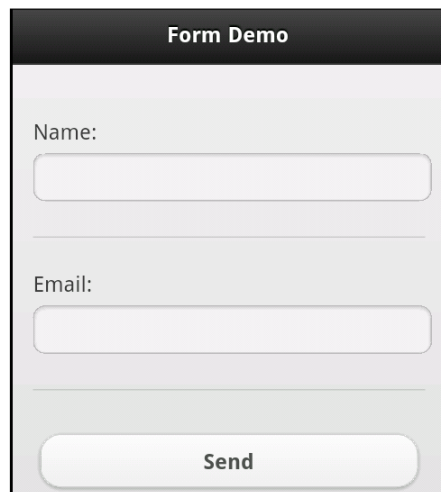

```
Listing 6-1: test1.html
<!DOCTYPE html>
<html>
  <head>
    <title>Form Example 1</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Form Demo</h1>
      </div>
      <div data-role="content">
        <form action="echo.cfm" method="post">
          <div data-role="fieldcontain">
```

```
<label for="name">Name:</label>
<input type="text" name="name" id="name" value="" />
</div>
<div data-role="fieldcontain">
  <label for="email">Email:</label>
  <input type="text" name="email" id="email" value="" />
</div>
<div data-role="fieldcontain">
  <input type="submit" name="submit" value="Send" />
</div>
</form>
</div>
</div>
</body>
</html>
```

As usual, the template begins with the proper includes and wraps the main content of our page with our specially marked up `div` tags. We will focus on the form fields with the main content area. It is recommended that every form field be wrapped with the following tag:

```
<div data-role="fieldcontain">
</div>
```

This will help jQuery Mobile align the label and form field. You'll see why in a moment. Our form has two text fields, one for name and one for e-mail. The last item is just the submit button. So outside of using a `fieldcontain` wrapper and ensuring we had labels for our form fields, nothing else special is going on here. Right away though you can see some pretty impressive changes to the form:

Notice how the labels are presented above the form fields. This gives the fields more space on the mobile device. Also notice the submit button is large and easy to click. If we rotate the device, jQuery Mobile updates the display to take advantage of the additional space:

Notice that the fields now line up directly to the right of their labels. So what happens when the form is submitted? As mentioned at the beginning of this chapter, we're making use of ColdFusion to handle responding to the form requests. Our `echo.cfm` template will simply loop over all the form fields and display them back out to the user:

```
Listing 6-2: echo.cfm
<div data-role="page">
  <div data-role="header">
    <h1>Form Result</h1>
  </div>
  <div data-role="content">
    <cfloop item="field" collection="#form#">
      <cfoutput>
        <p>
          The form field #field# has the value #form[field]#.
        </p>
      </cfoutput>
    </cfloop>
  </div>
</div>
```

If you do not want to install ColdFusion, you can simply edit the form action value in `listing 6-1` to point to a PHP file, or any other server-side processor. You may also simply change it to `test1.html`, the file itself. Nothing will happen when you submit, but you will not get an error either. Here's what the device will show after hitting submit:

Form Result

The form field EMAIL has the value
raymondcamden@gmail.com.

The form field FIELDNAMES has the value
NAME,EMAIL,SUBMIT.

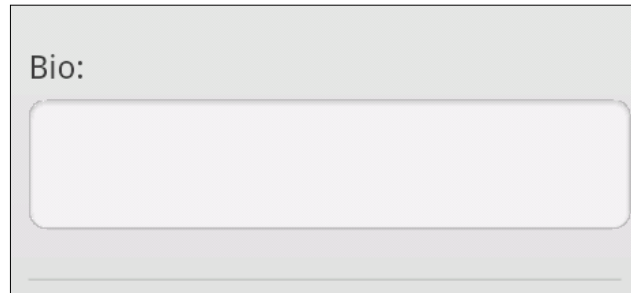

The form field SUBMIT has the value
Send.

The form field NAME has the value
Raymond.

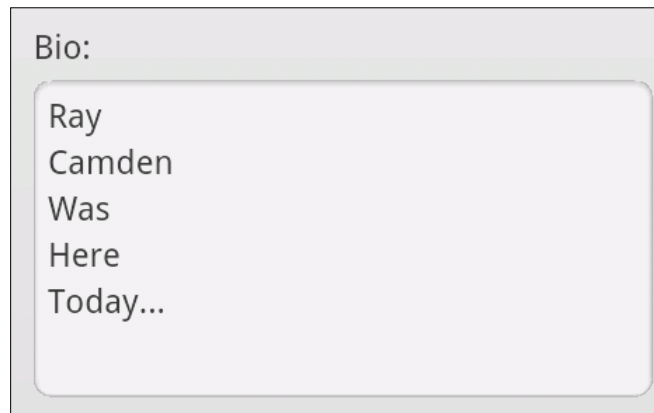

Another great example of how jQuery Mobile updates form fields is with `textarea`. `textarea`, by default, can be very difficult to work with on a mobile device, especially as the amount of text grows beyond the size of the `textarea` and a scroll bar is added. In the following code listing, we've simply modified the previous form to include a third item, a bio field that uses `textarea`. The complete file may be found in the book's code ZIP file. The following code snippet is the `div` block added after the previous two fields:

```
<div data-role="fieldcontain">
  <label for="bio">Bio:</label>
  <textarea name="bio" id="bio" />
</div>
```

When viewed on the device, the `textarea` expands to take in more width like the regular text fields, and grows taller:

A screenshot of a mobile device screen showing a form. The form has a light gray background. At the top left, the text 'Bio:' is displayed in a dark gray font. Below the label is a single-line text input field with rounded corners and a light gray border. The input field is currently empty.

But once you begin typing, and entering multiple lines of text, the `textarea` automatically expands:

A screenshot of a mobile device screen showing a form. The form has a light gray background. At the top left, the text 'Bio:' is displayed in a dark gray font. Below the label is a multi-line text input field with rounded corners and a light gray border. The input field contains the text 'Ray Camden Was Here Today...' on five lines. The input field has expanded to accommodate the multiple lines of text.

This is much easier to read than if scroll bars had been used. Now let's look at another common form option – radio buttons and checkboxes.

Working with radio buttons and checkboxes

Both radio buttons and checkboxes are also updated to work nicely on a mobile device, but require a tiny bit more code. In the earlier examples, we wrapped form fields with a `div` tag that made use of `data-role="fieldcontain"`. When working with radio buttons and checkboxes, one more tag is required:

```
<fieldset data-role="controlgroup">
```

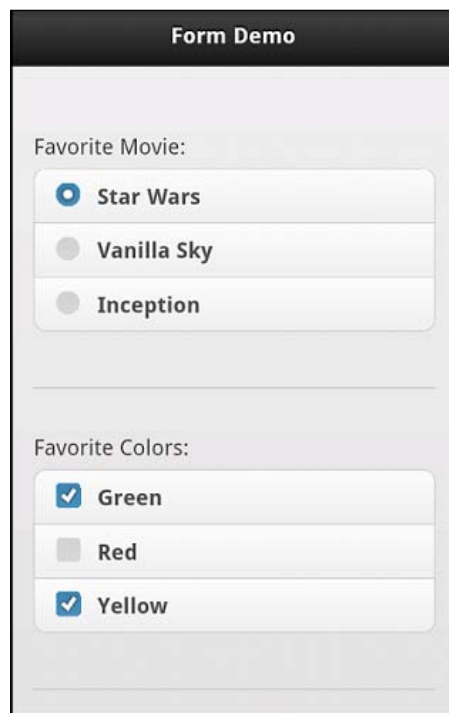

This fieldset tag will be used to group together your radio buttons or checkboxes. Listing 6-3 demonstrates one set of radio buttons and one checkbox group:

Listing 6-3: test3.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Form Example 3</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Form Demo</h1>
      </div>
      <div data-role="content">
        <form action="echo.cfm" method="post">
          <div data-role="fieldcontain">
            <fieldset data-role="controlgroup">
              <legend>Favorite Movie:</legend>
              <input type="radio" name="favoritemovie"
                id="favoritemovie1" value="Star Wars">
              <label for="favoritemovie1">Star Wars</label>
              <input type="radio" name="favoritemovie"
                id="favoritemovie2" value="Vanilla Sky">
              <label for="favoritemovie2">Vanilla Sky</label>
              <input type="radio" name="favoritemovie"
                id="favoritemovie3" value="Inception">
              <label for="favoritemovie3">Inception</label>
            </fieldset>
          </div>
          <div data-role="fieldcontain">
            <fieldset data-role="controlgroup">
              <legend>Favorite Colors:</legend>
              <input type="checkbox" name="favoritecolor"
                id="favoritecolor1" value="Green">
              <label for="favoritecolor1">Green</label>
            </fieldset>
          </div>
        </form>
      </div>
    </div>
  </body>
</html>
```

```
        <input type="checkbox" name="favoritecolor"
            id="favoritecolor2" value="Red">
        <label for="favoritecolor2">Red</label>
        <input type="checkbox" name="favoritecolor"
            id="favoritecolor3" value="Yellow">
        <label for="favoritecolor3">Yellow</label>
    </fieldset>
</div>
<input type="submit" name="submit" value="Send" />
</div>
</form>
</div>
</div>
</body>
</html>
```

Our form has two main questions – what is your favorite movie and what are your favorite colors? Each block is wrapped in the div tag we mentioned before. Inside this is the fieldset using data-role="controlgroup". Finally, you then have your radio and checkbox groups. It is important to include the labels within a proper label tab, as each of the previous examples have. Once rendered, jQuery Mobile groups these into a nice looking, singular control:

Notice the wide, clickable regions for each item. This makes it much easier to select items on a mobile device. Another interesting feature of both of these controls is the ability to turn them into horizontal button bars. In `test4.html`, both `fieldset` tags were modified to include a new data attribute:

```
<fieldset data-role="controlgroup" data-type="horizontal">
```

The image shows a mobile application interface titled "Form Demo". It contains two sections. The first section is labeled "Favorite Movie:" and features a horizontal button bar with three buttons: "Star Wars", "Vanilla Sky", and "Inception". The second section is labeled "Favorite Colors:" and features a horizontal button bar with three buttons: "Green", "Red", and "Yellow".

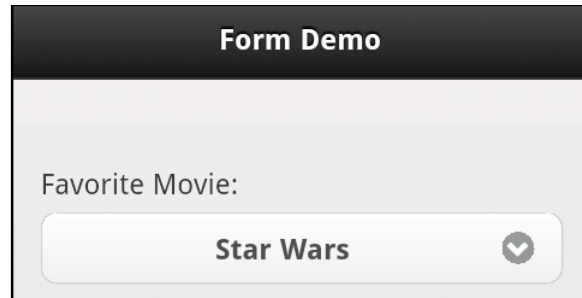

As you can see, the effect doesn't work well with the longer text in the first group, so be sure to test it.

Working with select menus

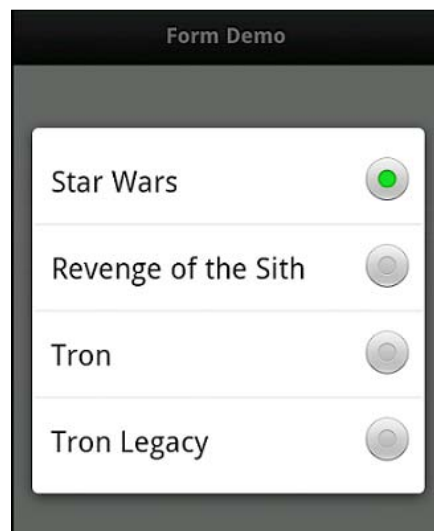

Yet another example of jQuery Mobile form enhancement is with select menus. As with our earlier examples, we make use of a `fieldcontain` div and `label` tag, but outside of that, the `select` tag is used as normal. The following code snippet is from `test5.html`:

```
<div data-role="fieldcontain">
  <label for="favmovie">Favorite Movie:</label>
  <select name="favmovie" id="favmovie">
    <option value="Star Wars">Star Wars</option>
    <option value="Revenge of the Sith">Revenge of the Sith</option>
    <option value="Tron">Tron</option>
    <option value="Tron Legacy">Tron Legacy</option>
  </select>
</div>
```

On the mobile device, the initial display of the select is modified to be easier to hit:

However, once clicked, the device's native menu will take over. This will look different on the platform you are using. The following screenshot shows how Android renders the menu:

Another option to use with select fields is grouping. jQuery Mobile allows you to vertically or horizontally group together multiple select fields. In both cases, all that's required is to wrap your select fields in a `fieldset` using the `data-role` of `controlgroup`, much like we did earlier for radio and checkboxes. The following code snippet is an example of a vertically aligned group of select fields:

```
<div data-role="fieldcontain">
  <fieldset data-role="controlgroup">
    <legend>Trip Setup:</legend>
    <label for="location">Location</label>
```

```

<select name="location" id="location">
  <option value="Home">Home</option>
  <option value="Work">Work</option>
  <option value="Moon">Moon</option>
  <option value="Airport">Airport</option>
</select>
<label for="time">Time</label>
<select name="time" id="time">
  <option value="Morning">Morning</option>
  <option value="Afternoon">Afternoon</option>
  <option value="Evening">Evening</option>
</select>
<label for="meal">Meal</label>
<select name="meal" id="meal">
  <option value="Meat">Meat</option>
  <option value="Vegan">Vegan</option>
  <option value="Kosher">Kosher</option>
</select>
</fieldset>
</div>

```

The rest of this template can be found in `test6.html`. The following screenshot shows how it looks:

Note how jQuery Mobile groups them together and nicely rounds the corners. The horizontal version can be achieved by adding a `data-type="horizontal"` attribute to the fieldset tag. It's also important to remove the div using `fieldcontain`. Here is an example (the complete file may be found in `test7.html`):

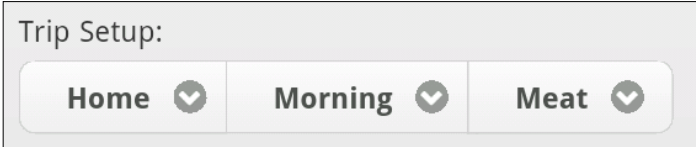

```

<div data-role="page">
  <div data-role="header">
    <h1>Form Demo</h1>
  </div>
  <div data-role="content">

```

```
<form action="echo.cfm" method="post">
  <fieldset data-role="controlgroup" data-type="horizontal">
    <legend>Trip Setup:</legend>
    <label for="location">Location</label>
    <select name="location" id="location">
      <option value="Home">Home</option>
      <option value="Work">Work</option>
      <option value="Moon">Moon</option>
      <option value="Airport">Airport</option>
    </select>
    <label for="time">Time</label>
    <select name="time" id="time">
      <option value="Morning">Morning</option>
      <option value="Afternoon">Afternoon</option>
      <option value="Evening">Evening</option>
    </select>
    <label for="meal">Meal</label>
    <select name="meal" id="meal">
      <option value="Meat">Meat</option>
      <option value="Vegan">Vegan</option>
      <option value="Kosher">Kosher</option>
    </select>
  </fieldset>
  <div data-role="fieldcontain">
    <input type="submit" name="submit" value="Send" />
  </div>
</form>
</div>
</div>
```

The following screenshot shows the result:

Trip Setup:		
Home ▼	Morning ▼	Meat ▼

Search, toggle, and slider fields

Along with taking regular form fields and making them work better, jQuery Mobile also helps make some of the newer HTML5 form fields work correctly across multiple browsers. While support still isn't nailed down on the desktop across every major browser, jQuery Mobile provides built-in support for search, toggle, and slider fields. Let's take a look at each one.

Search fields

The simplest of the three new fields, search fields simply adds a quick delete icon to the end of the field after you begin typing. Some devices will also put an hourglass icon in front as well, to help convey the idea of the field being used for some type of search. To use this field, simply switch your type from text to search. As in the following example from `test8.html`:

```
<div data-role="fieldcontain">
  <label for="name">Name:</label>
  <input type="search" name="name" id="name" value="" />
</div>
```

The following screenshot is the result. Notice that I've typed a bit and the field automatically adds a **Delete** icon at the end:

Flip toggle fields

Flip toggle fields are controls that flip back between one and two values. Creating a toggle field involves using a select control with a particular data-role value. Now, here is where things may get a bit confusing. To enable a select field to turn into a toggle field, you use `data-role="slider"`. In a little bit we're going to look at another slider control, but it uses a different technique. Just keep in mind that even though you'll be seeing `"slider"` in the HTML, it's really a toggle control we are creating. Let's look at a simple example. (You can find the complete source for this in `test9.html`):

```
<div data-role="fieldcontain">
  <label for="gender">Gender:</label>
  <select name="gender" id="gender" data-role="slider">
    <option value="0">Male</option>
    <option value="1">Female</option>
  </select>
</div>
```

Once rendered by jQuery Mobile, the following screenshots show the result, first with the default **Male** option, and then **Female**:

Slider fields

For the last of our special fields, we take a look at sliders. Like search fields, this is based on an HTML5 specification that works in some browsers and not others. jQuery Mobile simply makes it work everywhere. To enable this field, we take a regular text field and switch the type to "range". To give our slider a range we also provide a min and max value. You can also add additional color to the slider by adding the attribute: `data-highlight="true"`. The following code snippet is a sample. (You can find the complete file in `test10.html`):

```
<div data-role="fieldcontain">
  <label for="coolness">Coolness:</label>
  <input type="range" name="coolness" id="coolness" min="0" max="100"
    value="22" data-highlight="true">
</div>
```

The result is a slider control and an input field. Both allow you to modify the value between the minimum and maximum value:

Note – the HTML5 specification for the range supports a `step` attribute. While this works in some browsers, it is not yet directly supported by jQuery Mobile. In other words, jQuery Mobile won't try to add this support on a browser that doesn't have it built-in. You can add the attribute as long as you are aware it may not always work as intended.

Using native form controls

Now you've seen how far jQuery Mobile will go to enhance and empower your form fields to work better on mobile devices, but what if you don't like what jQuery Mobile does? What if you love its updates to buttons but despise its changes to drop-downs? Luckily jQuery Mobile provides a simple way to disable automatic enhancement. In each field you want to be left alone, simply add `data-role="none"` to the markup. So given the following HTML, the first item will be updated while the second will not:

```
<input type="submit" value="Awesome">
<input type="submit" value="Not So Awesome" data-role="none">
```

Another option is to disable it when jQuery Mobile is initialized. That option will be discussed in *Chapter 9, JavaScript Configuration and Utilities in jQuery Mobile*.

Working with "mini" fields

In the previous examples, we saw how jQuery Mobile automatically enhanced form fields to make them easier on smaller, touch based devices. In general, jQuery Mobile took your fields and made them nice and fat. While that's desirable most of the time, you may want to put your form fields on a bit of a diet. This is especially true for placing form fields in a header or footer. jQuery Mobile supports an attribute on any form field that creates a smaller version of the field: `data-mini="true"`. The following code snippet is a complete example:

```
<div data-role="fieldcontain">
  <label for="name">Name:</label>
  <input type="search" name="name" id="name" value="" />
</div>
<div data-role="fieldcontain">
  <label for="name">Name (Slim):</label>
  <input type="search" name="name" id="name" value="" data-
    mini="true" />
</div>
```

The result is a bit subtle, but you can see the height difference in the second field in the following screenshot:

The screenshot shows a mobile application interface with a dark header bar containing the text "Form Demo". Below the header, there are two text input fields. The first field is labeled "Name:" and the second is labeled "Name (Slim):". Both fields have a magnifying glass icon on the left side, indicating a search function. The second field is visually shorter than the first, demonstrating the height difference mentioned in the text.

This example may be found with the rest of the files in a file named `test12.html`.

Summary

In this chapter, we discussed forms and how they are rendered in a jQuery Mobile application. We discussed how jQuery Mobile automatically turns all form submissions into Ajax based calls and updates form fields to work better on mobile devices. Not only are all your form fields automatically updated, but you can also make use of new controls like the toggle, slider, and search inputs.

In the next chapter, we'll take a look at modal dialogs, widgets, and layout grids. These provide additional UI options for your mobile optimized site.

7

Creating Modal Dialogs, Grids, and Collapsible Blocks

In this chapter, we will look at dialogs, grids, and collapsible blocks. In the previous chapters we've dealt with pages, buttons, and form controls. While jQuery Mobile provides great support for them, there are even more UI controls you get within the framework.

In this chapter, we will:

- Discuss how to link to and create dialogs – also how to handle leaving them
- Demonstrate grids and how you can add them to your pages
- Show how collapsible blocks allow you to pack a lot of information in a small amount of space

Creating dialogs

Dialogs: at least under the jQuery Mobile framework: are small windows that cover an existing page. They typically provide a short message or question for the user. They will also typically include a button that allows the user to dismiss the dialog and return back to the site. Creating a dialog in jQuery Mobile is done by simply adding a simple attribute to a link: `data-rel="dialog"`. The following listing demonstrates an example:

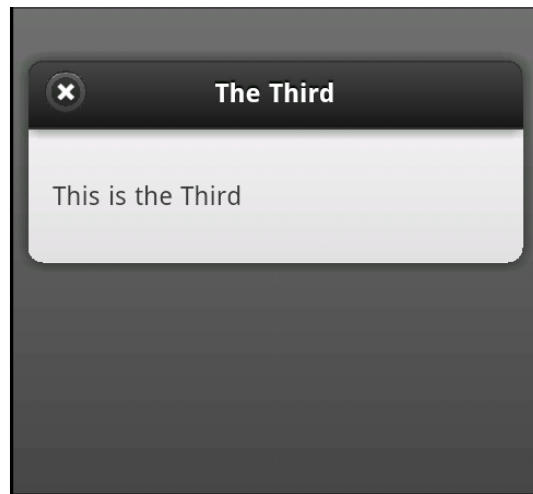

Listing 7-1: test1.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Dialog Test</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
```

```
<link rel="stylesheet" href="http://code.jquery.com/mobile/
latest/jquery.mobile.min.css" />
<script src="http://code.jquery.com/jquery-
1.7.1.min.js"></script>
<script src="http://code.jquery.com/mobile/latest/
jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page" id="first">
    <div data-role="header">
      <h1>Dialog Test</h1>
    </div>
    <div data-role="content">
      <p>
        <a href="#page2">Another Page (normal)</a>
      </p>
      <p>
        <a href="#page3" data-rel="dialog">A Dialog (dialog)</a>
      </p>
    </div>
  </div>
  <div data-role="page" id="page2">
    <div data-role="header">
      <h1>The Second</h1>
    </div>
    <div data-role="content">
      <p>
        This is the Second
      </p>
    </div>
  </div>
  <div data-role="page" id="page3">
    <div data-role="header">
      <h1>The Third</h1>
    </div>
    <div data-role="content">
      <p>
        This is the Third
      </p>
    </div>
  </div>
</body>
</html>
```

This is a simple, multi-page jQuery Mobile site. Notice how we link to the second and third page. The first link is typical. The second link, though, includes the `data-rel` attribute mentioned earlier. Notice that both the second and third page are defined in the usual manner. So the only change we have here is in the link. When that second link is clicked, the page is rendered completely differently:

Remember, that page wasn't defined differently. The change you see in the previous screenshot is driven by the change to the link itself. That's it! Clicking the little **X** button will hide the dialog and return the user back to the original page.

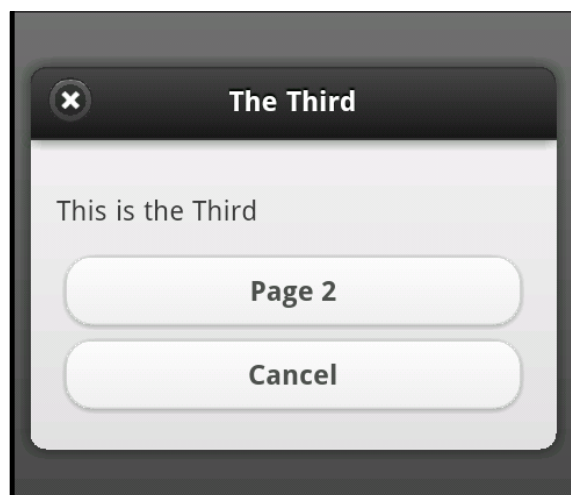

Any link within the page will handle closing the dialog as well. If you wish to add a cancel type button, or link, you can do so using `data-rel="back"` in the link. The target of the link should be to the page that launched the dialog. Listing 7-2 shows a modified version of the earlier template. In this one, we've simply added two buttons to the dialog. The first button will launch the second page, while the second one will act as a **Cancel** action.

Listing 7-2: test2.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Dialog Test (2)</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
```

```
<script src="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page" id="first">
    <div data-role="header">
      <h1>Dialog Test</h1>
    </div>
    <div data-role="content">
      <p>
        <a href="#page2">Another Page (normal)</a>
      </p>
      <p>
        <a href="#page3" data-rel="dialog">A Dialog (dialog)</a>
      </p>
    </div>
  </div>
  <div data-role="page" id="page2">
    <div data-role="header">
      <h1>The Second</h1>
    </div>
    <div data-role="content">
      <p>
        This is the Second
      </p>
    </div>
  </div>
  <div data-role="page" id="page3">
    <div data-role="header">
      <h1>The Third</h1>
    </div>
    <div data-role="content">
      <p>
        This is the Third
      </p>
      <a href="#page2" data-role="button">Page 2</a>
      <a href="#first" data-role="button" data-
        rel="back">Cancel</a>
    </div>
  </div>
</body>
</html>
```

The major change in this template is the addition of the buttons in the dialog, contained within `page3` `div`. Notice the first link is turned into a button, but outside of that is a simple link. The second button includes the addition of the `data-rel="back"` attribute. This will handle simply dismissing the dialog. The following screenshot shows how the dialog looks with the buttons added:

Laying out content with grids

Grids are one of the few features of jQuery Mobile that do not make use of particular data attributes. Instead, you work with grids simply by specifying CSS classes for your content.

Grids come in four flavors: Two column, Three column, Four column, and Five column. (You will probably not want to use the five column on a phone device. Save that for a tablet instead.)

You begin a grid with a `div` block that makes use of the class `ui-grid-x`, where `x` will be either `a`, `b`, `c`, or `d`. `ui-grid-a` represents a two column grid. `ui-grid-b` is a three column grid. You can probably guess what `c` and `d` create.

So to begin a two column grid, you would wrap your content with the following:

```
<div class="ui-grid-a">  
  Content  
</div>
```

Within the `div` tag, you then use a `div` for each "cell" of the content. The class for grid calls begins with `ui-block-X`, where `X` goes from `a` to `d`. `ui-block-a` would be used for the first cell, `ui-block-b` for the next, and so on. This works much like HTML tables.

Putting it together, the following code snippet demonstrates a simple two column grid with two cells of content:

```
<div class="ui-grid-a">
  <div class="ui-block-a">Left</div>
  <div class="ui-block-b">Right</div>
</div>
```

Text within a cell will automatically wrap. Listing 7-3 demonstrates a simple grid with a large amount of text in one of the columns:

Listing 7-3: test3.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Grid Test</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Grid Test</h1>
      </div>
      <div data-role="content">
        <div class="ui-grid-a">
          <div class="ui-block-a">
            <p>
              This is my left hand content. There won't be a lot of
              it.
            </p>
          </div>
        </div>
      </div>
    </div>
  </body>
</html>
```

```
</p>
</div>
<div class="ui-block-b">
  <p>
    This is my right hand content. I'm going to fill it
    with some dummy text.
  </p>
  <p>
    Bacon ipsum dolor sit amet andouille capicola spare
    ribs, short loin venison sausage prosciutto turducken
    turkey flank frankfurter pork belly short ribs. Venison
    frankfurter filet mignon, jowl meatball hamburger
    pastrami pork chop drumstick. Fatback pancetta boudin,
    ribeye shoulder capicola cow leberkäse bresaola spare
    ribs prosciutto venison ball tip jowl andouille. Beef
    ribs t-bone swine, tail capicola turkey pork belly
    leberkäse frankfurter jowl. Shankle ball tip sirloin
    frankfurter bacon beef ribs. Tenderloin beef ribs pork
    chop, pancetta turkey bacon short ribs ham flank chuck
    pork belly. Tongue strip steak short ribs tail swine.
  </p>
</div>
</div>
</div>
</div>
</body>
</html>
```

In the mobile browser, you can clearly see the two columns:

Working with other types of grids then is simply a matter of switching to the other classes. For example, a four column grid would be set up similar to the following code snippet:

```
<div class="ui-grid-c">
  <div class="ui-block-a">1st cell</div>
  <div class="ui-block-b">2nd cell</div>
  <div class="ui-block-c">3rd cell</div>
</div>
```

Again, keep in mind your target audience. Anything over two columns may be too thin on a mobile phone.

To create multiple rows in a grid, you simply repeat blocks. The following code snippet demonstrates a simple example of a grid with two rows of cells:

```
<div class="ui-grid-a">
  <div class="ui-block-a">Left Top</div>
  <div class="ui-block-b">Right Top</div>
  <div class="ui-block-a">Left Bottom</div>
  <div class="ui-block-b">Right Bottom</div>
</div>
```

Notice that there isn't any concept of a row. jQuery Mobile handles knowing that it should create a new row when the block starts over with the one marked `ui-block-a`. The following code snippet, Listing 7-4 is a simple example:

```
Listing 7-4:test4.html
<!DOCTYPE html>
<html>
  <head>
    <title>Grid Test (2)</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Grid Test</h1>
      </div>
      <div data-role="content">
        <div class="ui-grid-a">
          <div class="ui-block-a">
            <p>
              
            </p>
          </div>
          <div class="ui-block-b">
            <p>
              This is Raymond Camden. Here is some text about him. It
              may wrap or it may not but jQuery Mobile will make it
              look good. Unlike Ray!
            </p>
          </div>
        </div>
      </div>
    </div>
```

```
</div>
<div class="ui-block-a">
  <p>
    This is Scott Stroz. Scott Stroz is a guy who plays
    golf and is really good at FPS video games.
  </p>
</div>
<div class="ui-block-b">
  <p>
    
  </p>
</div>
</div>
</div>
</div>
</body>
</html>
```

The following screenshot shows the result:

Working with collapsible content

The final widget we will look at in this chapter supports collapsible content. This is simply content that can be collapsed and expanded. Creating a collapsible content widget is as simple as wrapping it in a div, adding `data-role="collapsible"`, and including a title for the content. Consider the following simple example:

```
<div data-role="collapsible">
  <h1>My News</h1>
  <p>This is the latest news about me...
</div>
```

Upon rendering, jQuery Mobile will turn the title into a clickable banner that can expand and collapse the content within. Let's look at a real example. Imagine you want to share the location of your company's primary address. You also want to include satellite offices. Since most people won't care about the other offices, we can use a simple collapsible content widget to hide the content by default. The following code snippet, Listing 7-5 demonstrates an example of this:

Listing 7-5: test5.html

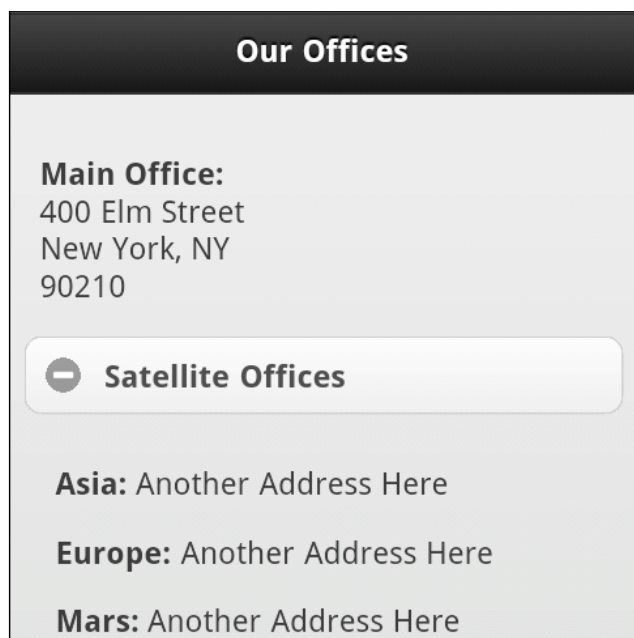

```
<!DOCTYPE html>
<html>
  <head>
    <title>Collapsible Content</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Our Offices</h1>
      </div>
      <div data-role="content">
        <p>
          <strong>Main Office:</strong><br/>
          400 Elm Street<br/>
          New York, NY<br/>
          90210
        </p>
```

```
<div data-role="collapsible">
  <h3>Satellite Offices</h3>
  <p>
    <strong>Asia:</strong>
    Another Address Here
  </p>
  <p>
    <strong>Europe:</strong>
    Another Address Here
  </p>
  <p>
    <strong>Mars:</strong>
    Another Address Here
  </p>
</div>
</div>
</div>
</body>
</html>
```

You can see that the other offices are all wrapped in the `div` tag using the new collapsible content role. When viewed, notice that they are hidden:

Clicking the + next to the title opens it, and can be clicked again to reclose it:

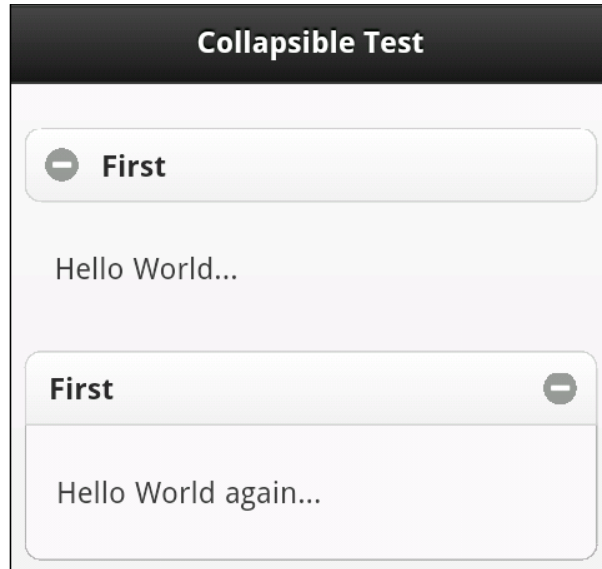

By default, jQuery Mobile will collapse and hide the content. You can, of course, tell jQuery Mobile to initialize the block open instead of closed. To do so, simply add `data-collapsed="false"` to the initial `div` tag. For example:

```
<div data-role="collapsible" data-collapsed="false">
  <h1>My News</h1>
  <p>This is the latest news about me...
</div>
```

This region will still have the ability to collapse and open, but will simply default to being opened initially.

Another option for collapsible content blocks is the ability to theme the content of the area that is collapsed. By providing a `data-content-theme` attribute, you can specify a background color that makes the region a bit more cohesive. Theming is covered in *Chapter 11, Theming jQuery Mobile*, but we can take a look at a quick example. In the following screenshot, the first region does not make use of the feature, while the second one does:

Notice that the icon is also shifted to the right. This demonstrates another option, `data-iconpos`. The following code snippet, found in the code folder as `test5-2.html`, demonstrates these options:

```
<div data-role="collapsible">
  <h3>First</h3>
  <p>
    Hello World...
  </p>
</div>
<div data-role="collapsible" data-content-theme="c" data-
  iconpos="right">
  <h3>First</h3>
  <p>
    Hello World again...
  </p>
</div>
```

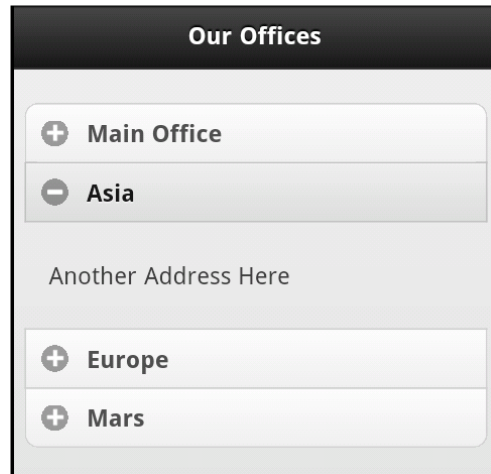

Finally, you can take multiple collapsible regions and combine them into one called an accordion. This is done by simply taking multiple collapsible blocks and wrapping them in a new `div` tag. This `div` tag makes use of `data-role="collapsible-set"` to make the inner blocks as one unit. Listing 7-6 demonstrates an example of this. It takes the earlier office address example and uses a collapsible set for each unique address:

Listing 7-6: test6.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Collapsible Content</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Our Offices</h1>
      </div>
      <div data-role="content">
        <div data-role="collapsible-set">
          <div data-role="collapsible">
            <h3>Main Office</h3>
            <p>
              400 Elm Street<br/>
              New York, NY<br/>
              90210
            </p>
          </div>
          <div data-role="collapsible">
            <h3>Asia</h3>
            <p>
              Another Address Here
            </p>
          </div>
          <div data-role="collapsible">
            <h3>Europe</h3>
            <p>
              Another Address Here
            </p>
          </div>
        </div>
      </div>
    </div>
```

```
        </div>
        <div data-role="collapsible">
            <h3>Mars</h3>
            <p>
                Another Address Here
            </p>
        </div>
    </div>
</div>
</div>
</div>
</body>
</html>
```

In listing 7-6, we simply wrap four collapsible blocks with a `div` tag that makes use of a collapsible set. Once done, jQuery Mobile will group them together and automatically close one once another is open:

Summary

In this chapter, we learned more about how jQuery Mobile enhances basic HTML to provide additional layout controls to our mobile pages. With dialogs, we learned how to provide a basic, quick, modal message to users. With grids, we learned a new way to easily layout content in columns. Finally, with the collapsible content blocks, we learned a cool way to share additional content without taking up as much screen space.

In the next chapter, we demonstrate a full, real example that creates a basic Note Tracker. It makes use of additional HTML5 features, as well as some of the UI tips you've learned over the past few chapters.

8

jQuery Mobile Configuration, Utilities, and JavaScript methods

In this chapter, we will look at how JavaScript can be used to further configure and enhance jQuery Mobile websites. So far we've made use of HTML and CSS to generate everything. Now we'll look at additional scripting that add additional functionality to your sites.

In this chapter, we will:

- Explain how jQuery Mobile sites can be configured via JavaScript
- Discuss the various JavaScript utilities that ship with jQuery Mobile and how they can be used
- Explain the APIs used to work with the enhanced jQuery Mobile form and widget controls

Configuring jQuery Mobile

jQuery Mobile does many things for you – from improving page navigation to changing how form controls work. All of this is done in an effort to make your content work better in a mobile environment. There will be times, however, when you do not want jQuery Mobile to do something, or you perhaps simply want to slightly tweak how the framework acts. That's where configuration comes in.

To configure a jQuery Mobile site, you begin by writing code that listens for the `mobileinit` event. This can be listened to using a normal jQuery event handler, similar to the following code snippet:

```
$(document).bind("mobileinit", function() {  
    //your customization here  
});
```

In order for this event to be captured, you must configure it before jQuery Mobile is actually loaded. The simplest way to do this, and the way recommended by the jQuery Mobile docs, is to simply place this code in a script loaded before the jQuery Mobile JavaScript library. The following code snippet shows what the header of our files typically look like:

```
<!DOCTYPE html>  
<html>  
  <head>  
    <title>Dialog Test</title>  
    <meta name="viewport" content="width=device-width, initial-  
      scale=1">  
    <link rel="stylesheet" href="http://code.jquery.com/mobile/  
      latest/jquery.mobile.min.css" />  
    <script src="http://code.jquery.com/jquery-  
      1.7.1.min.js"></script>  
    <script src="http://code.jquery.com/mobile/  
      latest/jquery.mobile.min.js"></script>  
  </head>
```

Notice the jQuery Mobile library is the last one loaded. We can simply add in a new script tag before it:

```
<!DOCTYPE html>  
<html>  
  <head>  
    <title>Dialog Test</title>  
    <meta name="viewport" content="width=device-width, initial-  
      scale=1">  
    <link rel="stylesheet" href="http://code.jquery.com/mobile/  
      latest/jquery.mobile.min.css" />  
    <script src="http://code.jquery.com/jquery-  
      1.7.1.min.js"></script>  
    <script src="config.js"></script>  
    <script src="http://code.jquery.com/mobile/  
      latest/jquery.mobile.min.js"></script>  
  </head>
```

Configuring jQuery Mobile is as simple as updating the `$.mobile` object. The following code snippet is a simple example:

```
$(document).bind("mobileinit", function() {
    $.mobile.someSetting="some value here";
});
```

This object contains a set of key/value pairs for the various settings that can be configured. You don't actually create it – it exists when the event handler is run. Another option is to make use of jQuery's `extend()` functionality, as shown in the following code snippet:

```
$(document).bind("mobileinit", function() {
    $.extend($.mobile, {
        someSetting:"some value here"
    });
});
```

Either form is ok and works absolutely the same. Use whichever feels more comfortable. Now, let's look at the various configuration options:

Settings	Use
<code>ns</code>	This is the namespace value used for data attributes. It defaults to nothing. You would specify a value here if you wanted to prefix the jQuery Mobile-recognized data attributes. So for example, if you wanted to use <code>data-jqm-role="page"</code> instead of <code>data-role="page"</code> , you would configure the <code>ns</code> value to be <code>jqm</code> .
<code>activeBtnClass</code>	This simply sets the class name used for buttons in the active state. The default for this value is <code>ui-btn-active</code> .
<code>activePageClass</code>	This sets the class name for pages that are currently being viewed. The default for this value is <code>ui-page-active</code> .
<code>ajaxEnabled</code>	We've discussed before how Ajax is used for both, page loads and form submissions. If you wish to disable this, set this value to <code>false</code> . The default, obviously, is <code>true</code> .
<code>allowCrossDomainPages</code>	A security setting that defaults to <code>false</code> , setting this to <code>true</code> allows for remote pages to be loaded via <code>\$.mobile.loadPage</code> . This is normally only required for PhoneGap applications that load content from another server.

Settings	Use
<code>autoInitializePage</code>	Normally, jQuery Mobile will run <code>\$.mobile.initializePage</code> on load. This displays the renders page. (At this time, this particular function isn't properly documented.) If you wish to disable this default value, set <code>autoInitializePage</code> to <code>false</code> . You will need to run <code>\$.mobile.initializePage</code> manually.
<code>defaultDialogTransition</code>	Specifies what transition should be used to show or hide dialogs. The default is <code>pop</code> . Possible values are: <code>fade</code> , <code>flip</code> , <code>pop</code> , <code>slide</code> , <code>slidedown</code> , and <code>slideup</code> .
<code>defaultPageTransition</code>	Like the previous option, this setting is used for transitions, this time for page loads. The default is <code>slide</code> and the options similar to the previous option are possible.
<code>gradea</code>	Used to determine what actually constitutes a "good" browser. This is handled by jQuery Mobile but if you want to overrule the framework, or define some other condition that must be met, you would provide a function here that returns a Boolean (<code>true</code> or <code>false</code>).
<code>hashListeningEnabled</code>	Refers to the ability to listen to changes in the <code>location.hash</code> property of the browser. jQuery Mobile handles this normally, but if the value is set to <code>false</code> , you can write your own code to respond to these changes.
<code>ignoreContentEnabled</code>	Normally jQuery Mobile automatically enhances everything it can. You can disable this in some cases at a control level, but you can also tell jQuery Mobile to ignore everything within a particular container by adding <code>data-enhance=true</code> . If you make use of this feature, then your configuration must be set <code>ignoreContentEnabled</code> to <code>true</code> . This tells jQuery Mobile to look for, and respect, that particular flag. This is set to <code>false</code> by default and allows jQuery Mobile to do its magic quite a bit faster.
<code>linkBindingEnabled</code>	jQuery Mobile typically listens to all link clicks. If you wish to disable this globally, you can do so with this setting.
<code>loadingMessage</code>	This specifies the text used when pages are loading. This is normally "loading", but you could use custom code here to check the user's locale and use a local specific version. However, the message is typically hidden. See the next setting for more information.

Settings	Use
<code>loadingMessageTextVisible</code>	When pages are loaded by jQuery Mobile, only a loading graphic is used. If you wish a message to be displayed as well, set this value to <code>true</code> . The default is <code>false</code> .
<code>loadingMessageTheme</code>	The theme to use for the page loading dialog. The default is <code>a</code> .
<code>minScrollBack</code>	jQuery Mobile will attempt to remember your scrolled position in a page when you return to it. This can be useful on a large page that the user returns to after visiting another page. By default, the scroll will be remembered if it is more than 150, the default.
<code>pageLoadErrorMessage</code>	This is a message shown to users if an error occurs when loading a page. The default is Error Loading Page , but could be changed for localization reasons. (Or any reason really.)
<code>pageLoadErrorMessageTheme</code>	The theme to use when a page load error dialog is displayed. The default is <code>e</code> .
<code>pushStateEnabled</code>	Tells jQuery Mobile to use the HTML5 <code>pushState</code> functionality instead of hash based changes for page navigation. This defaults to <code>true</code> .
<code>subPageUrlKey</code>	jQuery Mobile supports multiple pages within one file. In order to make these "virtual" pages bookmarkable, jQuery Mobile will append a value to the URL containing the prefix <code>ui-page</code> . So for example, <code>ui-page=yourpage</code> . This setting lets you customize the prefix.

That's quite a few options, but typically you will only need to configure one or two of these settings. Let's look at a simple example where a few of these are put to use. Listing 8-1 is the home page for the application. Note the use of the additional script tag to load in our configuration:

```
Listing 8-1: test1.html
<!DOCTYPE html>
<html>
  <head>
    <title>Page Transition Test</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.6.4.min.js"></script>
```

```
<script src="config.js"></script>
<script src="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.js"></script>
</head>
<body>
  <div data-role="page" id="first">
    <div data-role="header">
      <h1>Dialog Test</h1>
    </div>
    <div data-role="content">
      <p>
        <a href="#page2">Another Page</a><br/>
        <a href="test2.html">Yet Another Page</a><br/>
      </p>
    </div>
  </div>
  <div data-role="page" id="page2">
    <div data-role="header">
      <h1>The Second</h1>
    </div>
    <div data-role="content">
      <p>
        This is the Second. Go <a href="#first">first</a>.
      </p>
    </div>
  </div>
</body>
</html>
```

The file contains two pages, and links to another, `test2.html`. That page simply provides a link back so will not be included in the text. Now let's look at `config.js`:

```
Listing 8-2: config.js
$(document).bind("mobileinit", function() {
  $.mobile.defaultPageTransition = "fade";
  $.mobile.loadingMessage="Fetching page...";
});
```

In `config.js`, two settings are modified – the default page transition and the loading message for pages.

In an earlier chapter, we discussed forms and how jQuery Mobile automatically enhances controls. While you can suppress this enhancement on a control within your HTML, you can also tell jQuery Mobile a list of controls never to enhance. To set this list, specify a value for `$.mobile.page.prototype.options.keepnative`. The value should be a list of selectors. Any field that matches one of the selectors will *not* be enhanced.

Using jQuery Mobile utilities

Now that we've covered jQuery Mobile configuration, let's take a look at the utilities available to your applications. These are utilities provided by the framework and can be used in any application. You may not need them all (or any) on your site, but knowing they are there can help save you time in the future.

Page methods and utilities

Let's begin looking at methods and utilities related to pages and navigation between pages:

- `$.mobile.activePage`: This property is a reference to the current page.
- `$.mobile.changePage(page, options)`: This method is used to change to another page. The first argument, `page`, can be either a string (the URL), or a jQuery DOM object. The `options` argument is an optional object of key/value pairs. These options are:
 - `allowSamePageTransition`: Normally jQuery Mobile will not allow you to transition to the same page, but if set to `false`, this will be allowed.
 - `changeHash`: Determines if the URL should change.
 - `data`: Either a string or an object of values passed to the next page.
 - `data-url`: Value used for the URL in the browser. This is normally set by the page the user is being sent to. You can override this here.
 - `pageContainer`: jQuery Mobile will place pages within a DOM item that acts as a *bag* for all the pages. You can bypass this automatic collection and use another item in the DOM instead.
 - `reloadPage`: If a page already exists in the browser, jQuery Mobile will fetch it from memory. Setting this to `true` will force jQuery Mobile to reload the page.
 - `role`: jQuery Mobile will typically look for the `data-role` attribute of the page loaded. To specify another role, set this option.
 - `showLoadMsg`: Normally jQuery Mobile shows a loading message when a page is fetched. You can disable this by setting this value to `false`.
 - `transition`: What transition to use. Remember this can be configured at a global level as well.
 - `type`: We mentioned earlier that jQuery Mobile loads in new pages via an Ajax-based request. The `type` option allows you to specify the HTTP method used to load the page. The default is `get`.

- `$.mobile.loadPage(page, options)`: This is a lower-level function used when `$.mobile.changePage` is passed a string URL to load. Its first argument is the same as `$.mobile.changePage`, but its options are limited to `data`, `loadMsgDelay`, `pageContainer`, `reloadPage`, `role`, and `type`. Those options are the same as those listed in the previous option, except for `loadMsgDelay`. This value gives time for the framework to try to fetch a page via the cache first.
- `$.mobile.showPageLoadingMsg()` and `$.mobile.hidePageLoadingMsg()`: Either shows or hides the page loading message. The `showPageLoadingMsg` function allows for custom text, theming, and an icon only view.

In listing 8-2, a simple example of `$.mobile.changePage` is demonstrated:

Listing 8-2: test3.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Page Tester</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="third">
      <div data-role="header">
        <h1>Test</h1>
      </div>
      <div data-role="content">
        <input type="button" id="pageBtn" value="Go to page">
      </div>
    </div>
    <script>
      $("#pageBtn").click(function() {
        $.mobile.changePage("test2.html", {transition:"flip"});
      });
    </script>
  </body>
</html>
```

The page simply contains one button. At the bottom of the file is a jQuery event listener for that button. When clicked, `$.mobile.changePage` is used to load `test2.html` while making use of the flip transition.

Path and URL related utilities

These utilities are related to the current location, URL, or path of the application:

- `$.mobile.path.isAbsoluteUrl` and `$.mobile.path.isRelativeUrl`: These two functions look at a URL and allow you to check if they are either a full, or absolute URL, or a relative URL.
- `$.mobile.path.isSameDomain(first url, second url)`: Allows you to compare two URLs and determine if they are in the same domain. This method will notice http versus https and correctly consider these separate domains.
- `$.mobile.path.makePathAbsolute(relative path, absolute path)`: Takes a relative path, compares it to an absolute path, and returns an absolute path version of the relative path.
- `$.mobile.path.makeUrlAbsolute(relative url, absolute url)`: A slightly different form of the previous function, this utility works with absolute URLs instead.
- `$.mobile.path.parseUrl(url)`: URLs are made up of many different parts. This function will take either a full or relative URL and return an object containing the following properties: hash, host, hostname, href, pathname, port, protocol, and search. Along with these fairly typical URL properties, the function also returns the following properties:
 - `authority`: Contains the username, password, and host properties.
 - `directory`: Given the path portion of a URL, this will return just the directory.
 - `domain`: Contains the authority and protocol portions of the URL.
 - `filename`: Returns just the filename portion of the URL.
 - `hrefNoHash`: Given a URL with a hash, this returns the href minus the hash.
 - `hrefNoSearch`: Given a URL with a search property, this returns the href minus the search value.
 - `username` and `password`: Contains the username and password if present in the URL.

Listing 8-3 is a *tester* application. It contains form fields allowing you to test all of the methods previously discussed:

Listing 8-3: test4.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Path Tester</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.6.4.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="third">
      <div data-role="header">
        <h1>Test</h1>
      </div>
      <div data-role="content">
        <form>
          <div data-role="fieldcontain">
            <label for="isabsurl">Is Absolute URL?</label>
            <input type="text" name="isabsurl" id="isabsurl"
              value="" />
            <div id="isabsurlresult"></div>
          </div>
          <div data-role="fieldcontain">
            <label for="isrelurl">Is Relative URL?</label>
            <input type="text" name="isrelurl" id="isrelurl"
              value="" />
            <div id="isrelurlresult"></div>
          </div>
          <div data-role="fieldcontain">
            <label for="issamedomain">Is Same Domain?</label>
            <input type="text" name="issamedomain" id="issamedomain"
              value="" />
            <input type="text" name="issamedomain2"
              id="issamedomain2" value="" />
            <div id="issamedomainresult"></div>
          </div>
          <div data-role="fieldcontain">
```

```

        <label for="makepath">Make Path Absolute</label>
        <input type="text" name="makepath" id="makepath" value=""
            placeholder="Relative Path" />
        <input type="text" name="makepath2" id="makepath2"
            value="" placeholder="Absolute Path" />
        <div id="makepathresult"></div>
    </div>
    <div data-role="fieldcontain">
        <label for="makeurl">Make URL Absolute</label>
        <input type="text" name="makeurl" id="makeurl" value=""
            placeholder="Relative URL" />
        <input type="text" name="makeurl2" id="makeurl2" value=""
            placeholder="Absolute URL" />
        <div id="makeurlresult"></div>
    </div>
    <div data-role="fieldcontain">
        <label for="parseurl">Parse URL</label>
        <input type="text" name="parseurl" id="parseurl"
            value="" />
        <div id="parseurlresult"></div>
    </div>
</form>
</div>
<script>
    $("#isabsurl").keyup(function() {
        var thisVal = $(this).val();
        var isAbsUrl = $.mobile.path.isAbsoluteUrl(thisVal);
        $("#isabsurlresult").text(isAbsUrl);
    });
    $("#isrelurl").keyup(function() {
        var thisVal = $(this).val();
        var isRelUrl = $.mobile.path.isRelativeUrl(thisVal);
        $("#isrelurlresult").text(isRelUrl);
    });
    $("#issamedomain,#issamedomain2").keyup(function() {
        var domainVal1 = $("#issamedomain").val();
        var domainVal2 = $("#issamedomain2").val();
        var isSameDomain =
            $.mobile.path.isSameDomain(domainVal1,domainVal2);
        $("#issamedomainresult").text(isSameDomain);
    });
    $("#makepath,#makepath2").keyup(function() {
        var pathVal1 = $("#makepath").val();
        var pathVal2 = $("#makepath2").val();

```

```
var makePathResult =  
    $.mobile.path.makePathAbsolute(pathVal1,pathVal2);  
    $("#makepathresult").text(makePathResult);  
});  
$("#makeurl,#makeurl2").keyup(function() {  
    var urlVal1 = $("#makeurl").val();  
    var urlVal2 = $("#makeurl2").val();  
    var makeUrlResult =  
        $.mobile.path.makeUrlAbsolute(urlVal1,urlVal2);  
    $("#makeurlresult").text(makeUrlResult);  
});  
$("#parseurl").keyup(function() {  
    var thisVal = $(this).val();  
    var parsedUrl = $.mobile.path.parseUrl(thisVal);  
    var s = "";  
    for (k in parsedUrl) {  
        s+= k+"="+parsedUrl[k]+"<br/>";  
    }  
    $("#parseurlresult").html(s);  
});  
</script>  
</body>  
</html>
```

Listing 9-4 is a bit long, but it's really pretty simple. Each `fieldcontain` block consists of one particular test of the path methods and utilities. In the bottom half of the template you can see we've made use of `keyup` event listeners to monitor changes to these fields and run each test. You can use this template to see how these methods react based on different inputs. The following screenshot shows an example:

The screenshot shows a mobile application interface with a dark header bar labeled "Test". Below the header, there are three test blocks, each with a label, a text input field, and a result display. The first block is "Is Absolute URL?" with input "/foo" and result "false". The second block is "Is Relative URL?" with input "/foo" and result "true". The third block is "Is Same Domain?" with input "http://cnn.com" and result "true". Each input field is a rounded rectangle with a light gray border. The result text is displayed below the input field.

Test	Input	Result
Is Absolute URL?	/foo	false
Is Relative URL?	/foo	true
Is Same Domain?	http://cnn.com	true

Miscellaneous utilities

There are a few more utilities you may want to know about:

- `$.mobile.fixedToolbars.hide()` and `$.mobile.fixedToolbars.show()`: Either show or hide fixed toolbars. Both utilities can take a Boolean argument that specifies if the hide (or show) action takes place immediately. If not specified (or false is passed) then the toolbars will animate as they hide or show.
- `$.mobile.silentScroll(position)`: Scrolls the page to a certain y-position. The term *silent* here refers to the fact that this method will *not* fire any code listening for scroll events.
- `jqmData()` and `jqmRemoveData()`: Due to jQuery Mobile's heavy use of data attributes for various features, "regular" usage of jQuery's data functions should be replaced with these instead. They handle recognizing any update to the default namespace as well.

jQuery widget and form utilities

We've mentioned, numerous times, how jQuery Mobile automatically updates various items and supports things like lists and collapsible content. One of the things you may run into, however, is trying to get jQuery Mobile to work with content loaded *after* the page is rendered. So, for example, imagine a list view that has data added to it via some JavaScript code. Listing 8-4 demonstrates a simple example of this. It has a `listview` with a few items in it, but also a form by which a person could add new entries:

Listing 8-4: test5.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>List Updates</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="third">
      <div data-role="header">
        <h1>List Updates</h1>
```

```
</div>
<div data-role="content">
  <ul id="theList" data-role="listview" data-inset="true">
    <li>Initial</li>
    <li>Item</li>
  </ul>
  <form>
    <div data-role="fieldcontain">
      <label for="additem">New Item</label>
      <input type="text" name="additem" id="additem"
        value="" />
    </div>
    <input type="button" id="testBtn" value="Add It">
  </form>
</div>
</div>
<script>
  $("#testBtn").click(function() {
    var itemToAdd = $.trim($("#additem").val());
    if(itemToAdd == "") return;
    $("#theList").append("<li>" + itemToAdd + "</li>");
  });
</script>
</body>
</html>
```

When initially loaded, notice everything seems fine:

However, the following screenshot shows what happens when an item is added to the end of the list:

As you can see, the new item was indeed added to the end of the list, but it wasn't drawn correctly. This brings up a critical point. jQuery Mobile parses your code for data attributes and checks for form fields once. After it has done so, it considers its work done. Luckily, there is a standard way for these UI items to be updated. For our `listview` it is a simple matter of calling the `listview` method on the list itself. The `listview` method can be used to turn a new list into a `listview`, or to refresh an existing `listview`. To refresh our `listview`, we'd simply modify the code, as shown in the following code snippet:

```
<script>
  $("#testBtn").click(function() {
    var itemToAdd = $.trim($("#additem").val());
    if(itemToAdd == "") return;
    $("#theList").append("<li>"+itemToAdd+"</li>");
    $("#theList").listview("refresh");
  });
</script>
```

You can find the previous code snippet in `test6.html`. The following screenshot shows how the application handles the new item:

That `listview` method could also be used for completely new lists. Consider the following code snippet listing 8-5:

```
Listing 8-5: test7.html
<!DOCTYPE html>
<html>
  <head>
    <title>List Updates</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="third">
      <div data-role="header">
        <h1>List Updates</h1>
      </div>
```

```
<div data-role="content" id="contentDiv">
  <input type="button" id="testBtn" value="Add A List">
</div>
</div>
<script>
  $("#testBtn").click(function() {
    $("#contentDiv").append("<ul data-role='listview' data-
      inset='true' id='theList'><li>Item One</li><li>Item
      Two</li></ul>");
    $("#theList").listview();
  });
</script>
</body>
</html>
```

In this example, a completely new list is appended to the `div` tag. Notice that we still include the proper `data-role`. But, this by itself, is not enough. We follow up the HTML insertion with a call to the `listview` method to enhance the list just added.

Similar APIs exist for other fields. For example, new buttons added to a page can be enhanced by calling the `button()` method on them. In general, assume any changes to enhanced controls will need to be updated via their respective JavaScript APIs.

Summary

In this chapter, we (finally!) broke out some JavaScript. We looked at how you can configure various jQuery Mobile settings, what utilities exist, and how to handle post-rendered updates to enhanced controls.

In the next chapter, we'll continue working with JavaScript and look at the various events your code can listen to.

9

Working with Events

In this chapter, we will look at how events work in jQuery Mobile. While developers obviously have access to regular events (button clicks, and so on), jQuery Mobile also exposes its own events for developers to make use of.

In this chapter, we will:

- Discuss touch, swipe, scroll, and other physical events
- Discuss page events

Working with physical events

For the first part of this chapter, we will focus on the "physical" events, or events related to touch and other actions done with a device.

For those of you who have been testing jQuery Mobile using a regular browser, please note that some of the following examples will not work properly on a desktop browser. If you wish, you can download and install emulators for various mobile phone types. For example, Android has an SDK that supports creating virtual mobile devices. Apple also has a way to simulate an iOS device. Setting up and installing these emulators are beyond the scope of this chapter, but it is certainly an option. Of course, you can also use a real hardware device as well.

The physical events include the following:

- `tap` and `taphold`: `tap` represents what it sounds like – a quick physical touch on the web page. `taphold` is a longer touch. Many applications will make use of two separate actions – one for `tap` and one for `taphold`.
- `swipe`, `swipeleft`, and `swiperight`: These represent swipes, or a finger movement across most of the devices. The `swipe` event is a generic one, whereas `swipeleft` and `swiperight` represent a swipe in a specific direction. There is no support for a swipe up or down event.
- `scrollstart` and `scrollstop`: Respectively handle the beginning and end of scrolling a page.
- `orientationchange`: Fired when the device's orientation changes.
- `vclick`, `vmousedown`, `vmouseup`, `vmousemove`, `vmousecancel`, and `mouseover`: All of these are "virtual" events meant to abstract away checking for either touch or mouse click events. As these are mainly just aliases for click and touch events, they will not be demonstrated.

Now that we've listed the basic physical events, let's start looking at a few examples.

Listing 9-1 demonstrates a simple example of the `tap` and `taphold` events:

```
Listing 9-1: test1.html
<!DOCTYPE html>
<html>
  <head>
    <title>Tap Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Tap Tests</h1>
      </div>
```

```
<div data-role="content">
  <p>
    Tap anywhere on the page...
  </p>
  <p id="status"></p>
</div>
</div>
<script>
  $("body").bind("tap", function(e) {
    $("#status").text("You just did a tap event!");
  });
  $("body").bind("taphold", function(e) {
    $("#status").text("You just did a tap hold event!");
  });
</script>
</body>
</html>
```

This template is rather simple. The page has some explanatory text asking the user to tap on it. Beneath it is an empty paragraph. Note though the two binds at the end of the document. One listens for `tap` while the other listens for `taphold`. The user can do either action and a different status message is displayed. While rather simple, this gives you a good idea of how you could respond differently based on how long the user holds their finger down. (The time for the `taphold` event to fire is around one second):

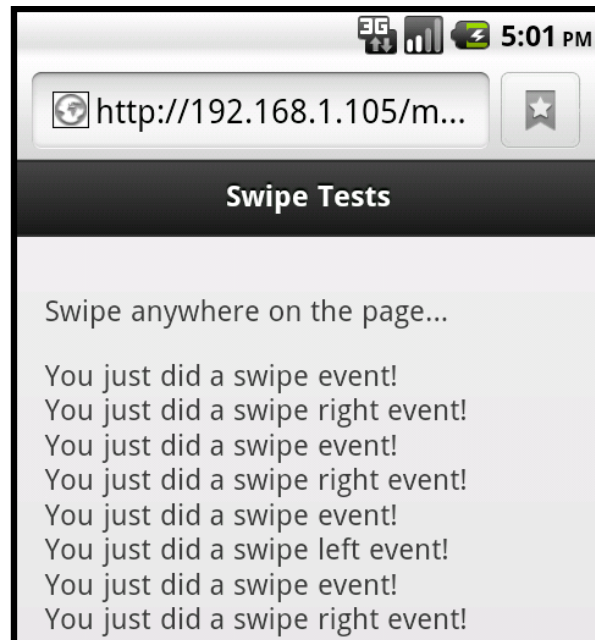

Now let's look at Listing 9-2, an example of swipe events:

Listing 9-2: test2.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Swipe Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Swipe Tests</h1>
      </div>
      <div data-role="content">
        <p>
          Swipe anywhere on the page...
        </p>
        <p id="status"></p>
      </div>
    </div>
    <script>
      $("body").bind("swipe", function(e) {
        $("#status").append("You just did a swipe event!<br/>");
      });
      $("body").bind("swipeleft", function(e) {
        $("#status").append("You just did a swipe left event!<br/>");
      });
      $("body").bind("swiperight", function(e) {
        $("#status").append("You just did a swipe right
        event!<br/>");
      });
    </script>
  </body>
</html>
```

This example is pretty similar to the previous one, except now our event handlers listen for `swipe`, `swipeleft`, and `swiperight`. One important difference is that we append to the status div instead of simply setting it. Why? A `swiperight` or `swipeleft` event is automatically a `swipe` event. If we simply set the text in the paragraph, one would wipe out the other. The following screenshot shows how the device looks after a few swipes:

How about a more complex example? Consider the following code snippet, Listing 9-3:

```
Listing 9-3: test3.html
<!DOCTYPE html>
<html>
  <head>
    <title>Swipe Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
```

```
<body>
  <div data-role="page" id="first">
    <div data-role="header">
      <h1>First</h1>
    </div>
    <div data-role="content">
      <p>
        Swipe to navigate
      </p>
    </div>
  </div>
  <div data-role="page" id="second">
    <div data-role="header">
      <h1>Second</h1>
    </div>
    <div data-role="content">
      <p>
        Swipe to the right...
      </p>
    </div>
  </div>
  <script>
    $("body").bind("swipeleft swiperight", function(e) {
      var page = $.mobile.activePage[0];
      var dir = e.type;
      if(page.id == "first" && dir == "swipeleft")
        $.mobile.changePage("#second");
      if(page.id == "second" && dir == "swiperight")
        $.mobile.changePage("#first");
    });
  </script>
</body>
</html>
```

In this example, we've got a file that includes two separate pages, one with the id `first` and the other with the id `second`. Notice we have no links. So how do we navigate? With swipes! Our event handler is now listening for both `swipeleft` and `swiperight`. We first grab the active page using `$.mobile.activePage`, as described in *Chapter 8, JavaScript Configuration and Utilities in jQuery Mobile* on methods and utilities. The `[0]` at the end refers to the fact that the value is actually a jQuery Selector. Using `[0]` grabs the actual DOM item. The event type will be either `swipeleft` or `swiperight`. Once we know that, we can actively move the user around depending on what page they are currently on and in what direction they swiped.

Now let's look at scrolling. You can detect when a scroll starts and when one ends. Listing 9-4 is another simple example of this in action:

Listing 9-4: test4.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Scroll Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Scroll Tests</h1>
      </div>
      <div data-role="content">
        <p>
          Scroll please....<br/>
          <br/>
          <br/>
          (Many <br/> tags removed to save space!)
          <br/>
          <br/>
        </p>
        <p id="status"></p>
      </div>
    </div>
    <script>
      $("body").bind("scrollstart", function(e) {
        $("#status").append("Start<br/>");
      });
      $("body").bind("scrollstop", function(e) {
        $("#status").append("Done!<br/>");
      });
    </script>
  </body>
</html>
```

This template is pretty similar to `test1.html`, the tap tester, except now we've listened to `scrollstart` and `scrollstop`. Also note the list of `
` tags. In the real source file, there are many of these. This will ensure that the page is actually scrollable when you test. When the scrolling will start and end, we simply append to another status div. (Please note that currently DOM manipulation is listed as being buggy when listening to `scrollstart`. The previous example may not work in iOS, but works fine on Android.)

Now let's look at orientation. While the previous examples should be (mostly) testable on your desktop, you will definitely need a real mobile device to test the next example:

Listing 9-5: `test5.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Orientation Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Orientation Tests</h1>
      </div>
      <div data-role="content">
        <p>
          Tilt this sideways!
        </p>
        <p id="status"></p>
      </div>
    </div>
    <script>
      $(window).bind("orientationchange", function(e,type) {
        $("#status").html("Orientation changed to "+e.orientation);
      });
    </script>
  </body>
</html>
```

The critical part of the previous code listing is the JavaScript at the end, specifically the event listener for changing orientation. This is not actually a jQuery Mobile supported event but something supported by the browser itself. Once the event listener is attached, you can do whatever you wish based on the orientation of the device. The following screenshot is the demonstration:

Handling page events

Now that we've discussed physical type events, it's time to turn our attention to page events. Remember that jQuery Mobile has its own concept of pages. In order to give developers even more control over how pages work within jQuery Mobile, numerous page events are supported. Not all will necessarily be useful in your day to day development. In general, page events can be split into the following categories:

- **load:** These are events related to the loading of a page. They are `pagebeforeload`, `pageload`, and `pageloadfailed`. `pagebeforeload` is fired prior to a page being requested. Your code can either approve or deny this request based on whatever logic may make sense. If a page is loaded, then `pageload` is fired. Conversely, `pageloadfailed` will be fired on any load that does not complete.
- **change:** These events are related to the change from one page to another. They are: `pagebeforechange`, `pagechange`, and `pagechangefailed`. As before, the `pagebeforechange` function acts as a way to programmatically decline the event. If done, the `pagechangefailed` event is fired. `pagebeforechange` is fired *before* the `pagebeforeload` event. `pagechange` will fire after the page is displayed.
- **transition:** Events related to the movement, or transition, from one page to another. They are: `pagebeforeshow`, `pageshow`, `pagebeforehide`, and `pagehide`. Both `pagebeforeshow` and `pagebeforehide` run prior to their related events but unlike `pagebeforeload` and `pagebeforechange`, they can't actually prevent the next event.

- **init:** As it has been shown many times in this book, jQuery Mobile performs multiple updates to basic HTML to optimize it for mobile displays. These are initialization related events. The events you can listen to are: `pagebeforecreate`, `pagecreate`, and `pageinit`. `pagebeforecreate` fires before any of the automatic updates are fired on your controls. This allows you to manipulate your HTML via Javascript beforehand. `pagecreate` is fired after page content exists in the DOM, but still before the layout has been updated by jQuery Mobile. The official docs recommend this as the place to do any custom widget handling. Finally, `pageinit` will run after the initialization has been completed.
- **remove:** There is one event for this category - `pageremove`. This event is fired before jQuery Mobile removes an inactive page from the DOM. You can listen to this event to prevent the framework from removing the page.
- **layout:** The final category is related to layout and has one event - `updatelayout`. This is typically fired by other layout changes as a way to let the page know it needs to update itself.

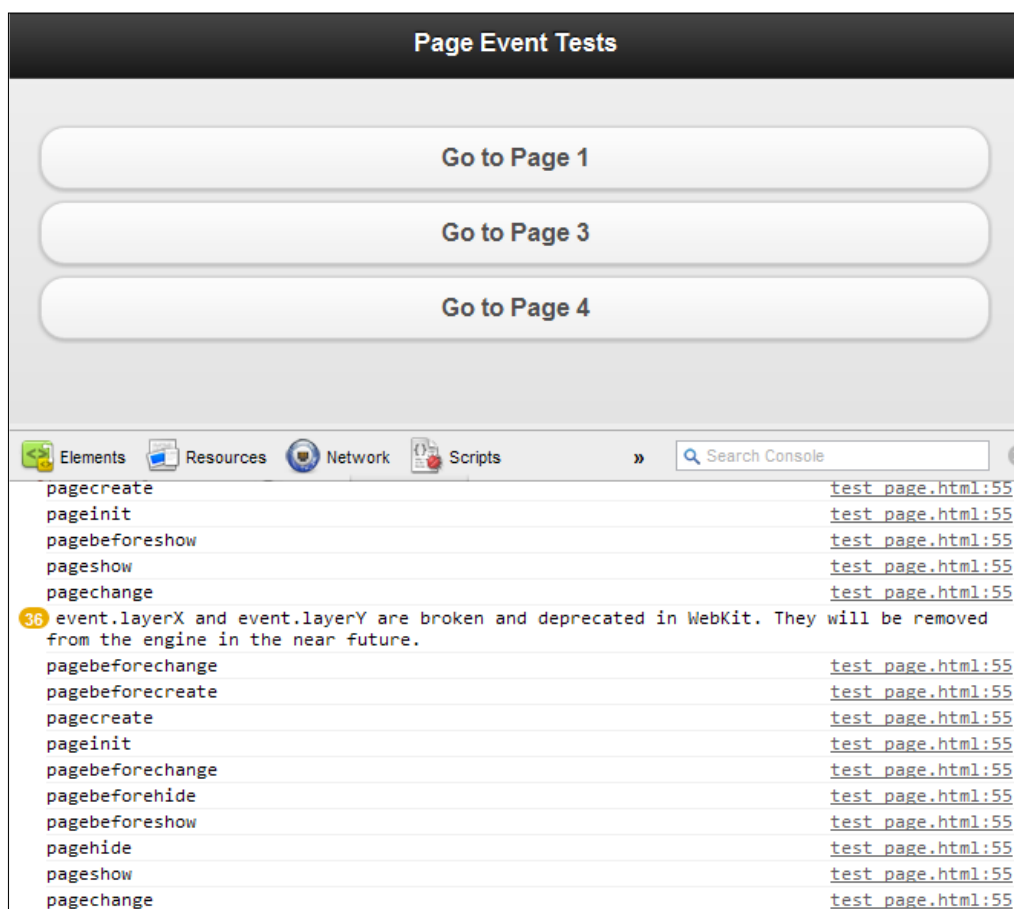

That's quite a lot! A simple way to look at these events in action would be to simply listen to all of them. In Listing 9-6, we have a simple example of this in action:

Listing 9-6: `test_page.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Page Event Tests</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="first">
      <div data-role="header">
        <h1>Page Event Tests</h1>
      </div>
```

```
<div data-role="content">
  <p>
    <a href="#page2" data-role="button">Go to Page 2</a>
    <a href="test_pagea.html" data-role="button">
      Go to Page 3</a>
    <a href="test_pageb.html" data-role="button">
      Go to Page 4</a>
    <a href="test_pageDOESNTEXIST.html" data-role="button">
      Go to Page Failed</a>
  </p>
</div>
</div>
<div data-role="page" id="page2">
  <div data-role="header">
    <h1>Page Event Tests</h1>
  </div>
  <div data-role="content">
    <p>
      <a href="#first" data-role="button">Go to Page 1</a>
      <a href="test_pagea.html" data-role="button">
        Go to Page 3</a>
      <a href="test_pageb.html" data-role="button">
        Go to Page 4</a>
    </p>
  </div>
</div>
</div>
<script>
  $(document).bind("pagebeforeload pageload pageloadfailed
    pagebeforechange pagechange pagechangefailed pagebeforeshow
    pagebeforehide pageshow pagehide pagebeforecreate pagecreate
    pageinit pageremove updatelayout", function(e) {
    console.log(e.type);
  });
</script>
</body>
</html>
```

This template is part of a four-page, three-file simple application that has buttons linking to each of the other pages. The other pages may be found in the ZIP file you downloaded. In order to test this application, you **should** use a desktop browser with console support. That's any version of Chrome, recent Firefox browsers (or Firefox with Firebug), and the latest Internet Explorer. A full explanation of the browser console wouldn't fit in this chapter, but you can think of it as a hidden away debugging log useful for recording events and other messages. In this case, we've told jQuery to listen for all of our jQuery Mobile page events. We then log the specific event type to the console. After clicking around a bit, the following screenshot shows how the console log looks in a Chrome browser:

Opening the console in Chrome is simple. Click on the monkey wrench icon in the upper right corner of the browser. Select **Tools** and then **JavaScript Console**. Open the console up before testing these files yourself and you can monitor the page events as they happen in real time.

What about \$(document).ready?

If you are a jQuery user, you may be curious how `$(document).ready` comes into play with a jQuery Mobile site. Almost all jQuery applications use `$(document).ready` for initialization and other important setup operations. However, in a jQuery Mobile application, this will not work well. Since Ajax is used to load pages, `$(document).ready` is only really effective for the *first* page. Therefore, the `pageInit` event should be used in cases where you would have used `$(document).ready` in the past.

Creating a real example

So what about a real example? Our next set of code is going to demonstrate how to create a simple, but dynamic, jQuery Mobile web site. The content will be loaded via Ajax. Normally this would be dynamic data, but for our purposes we'll use simple static files of JSON data. JSON, stands for JavaScript Object Notation, is a way to represent complex data as simple strings. Listing 9-7 is the application's home page:

Listing 9-7: test_dyn.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Test Dynamic</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
    <div data-role="page" id="homepage">
      <div data-role="header">
        <h1>Dynamic Pages</h1>
      </div>
      <div data-role="content">
        <ul id="peopleList" data-role="listview"
          data-inset="true"></ul>
      </div>
    </div>
    <script>
      $('#homepage').bind("pagebeforecreate", function(e) {
```

```
//load in our people
$.get("people.json", {}, function(res,code) {
    var s = "";
    for (var i = 0; i < res.length; i++) {
        s+="- <a href='test_people.html
            ?id="+res[i].id+"'>"+res[i].name+"</a></li>";
    }
    $("#peopleList").html(s).listview("refresh");
}, "json");
});
$("#personpage").live("pagebeforeshow", function(e) {
    var thisPage = $(this);
    var thisUrl = thisPage.data("url");
    var thisId = thisUrl.split("=")[1];
    $.get("person"+thisId+".json", {}, function(res, code) {
        $("h1",thisPage).text(res.name);
        s = "<p>"+res.name + " is a "+res.gender+" and
            likes "+res.hobbies+"</p>";
        $("#contentArea", thisPage).html(s);
    }, "json");
    });
</script>
</body>
</html>

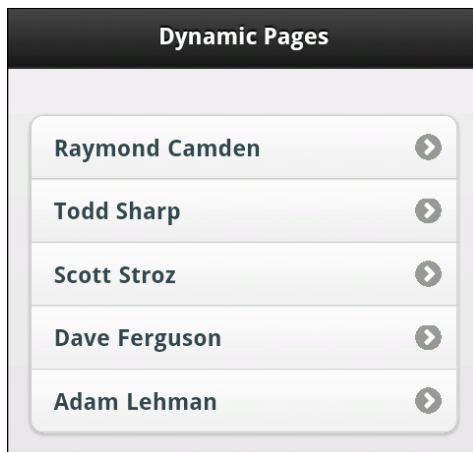

```

The first thing you may notice about this jQuery Mobile page is that there isn't any actual content. Not within the jQuery Mobile page's content block at least. There's a `listview` but no actual content. So where's the content going to come from? At the bottom of the page you can see two event listeners. For now let's just focus on the first one.

The code here binds to the `pagebeforecreate` event that jQuery Mobile fires for pages. We've told jQuery Mobile to run this event before it creates the page. This event will run once and only once. Within this event we use the jQuery `get` feature to do an Ajax request to the file `people.json`. That file is simply an array of names in JSON format:

```
[{"id":1,"name":"Raymond Camden"}, {"id":2,"name":"Todd
Sharp"}, {"id":3,"name":"Scott Stroz"}, {"id":4,"name":"Dave
Ferguson"}, {"id":5,"name":"Adam Lehman"}]
```

Each name has both an ID and the actual name value. When loaded by jQuery, this is turned into an actual array of simple objects. Looking back at the event handler, you can see that we simply loop over this array and create a string representing a set of `li` tags. Note that each one has a link to `test_people.html` as well as a dynamic name. Also note the links themselves are dynamic. They include each person's ID value as retrieved from the JSON string:

It was mentioned earlier, but take note of the call to `listview("refresh")`:

```
$("#peopleList").html(s).listview("refresh");
```

Without the `listview("refresh")` portion, the items we added to the listview would not be styled correctly.

Let's take a quick look at `test_people.html` next:

Listing 9-8: `test_people.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Test Dynamic</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-
      1.7.1.min.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
  </head>
  <body>
```

```
<div data-role="page" id="personpage">
  <div data-role="header">
    <h1></h1>
  </div>
  <div data-role="content" id="contentArea">
  </div>
</div>
</body>
</html>
```

As with our last page, this one is pretty devoid of content. Note that both the header and the content area are blank. But, if you remember the second event handler in `test_dyn.html`, we have support to load the content here. This time we used the `pagebeforeshow` event. Why? We want to run this code before every display of the page. We need to know what particular person to load. If you remember, the ID of the person was passed in the URL. We can fetch that via a data property, `url`, that exists on the page object. This returns the complete URL, but all we care about is the end of it – our ID. So we split the string and grab the last value. Once we have, we can then load in a particular JSON file for each person. The form of this filename is `personX.json`, where `X` is the number 1 through 5. The following line of code is one example:

```
{ "name": "Raymond Camden", "gender": "male", "hobbies": "Star Wars" }
```

Obviously, a real person object would have a bit more data. Once we fetch this string, we can then parse it and lay out the result on the page itself:

Summary

In this chapter, we looked into events that jQuery Mobile application can listen and respond to. These events include physical types (scrolling, orientation, touching) and page based ones as well.

In the next chapter, we'll look at how jQuery Mobile sites are themed – both out of the box themes and custom ones as well.

10

Moving further with the Notekeeper Mobile Application

In this chapter, we're going to begin assembling everything we've learned about lists, forms, pages, and content formatting thus far into a usable "mobile application"; the Notekeeper application.

In this chapter, we will:

- Accept user input using forms
- Store user inputted data locally using the HTML5 localStorage functionality
- Demonstrate how to add, edit, and remove items from the page dynamically

What is a mobile application?

Before writing our first mobile application, perhaps we should define what one is. Wikipedia says that a mobile application is *Software that is developed for small low-power handheld devices such as personal digital assistants, enterprise digital assistants or mobile phones*. While it's true that jQuery Mobile apps are written in HTML, CSS, and JavaScript, that doesn't prevent them from being sophisticated pieces of software. They're certainly developed with mobile devices in mind.

Some critics might note that it can't really be software unless it's "installed". As you'll see later in the book, jQuery Mobile applications can actually be installed on a wide array of devices (including iOS, Android, and Windows Mobile) when coupled with the open source library PhoneGap. This means that you'll be able to have your cake and eat it too. You might be asking yourself if code written using jQuery Mobile can be considered software, and as you'll find out in this chapter, the answer is yes.

Designing your first mobile application

The goal of any piece of software is to meet a need. Gmail met a need by freeing users from a single computer and letting them check their e-mail from any web browser. Photoshop met a need by allowing users to manipulate photos in ways no one had ever done. Our Notekeeper application meets a need by allowing us to record simple notes for later reference. I know, sort of a letdown by comparison but we've got to start somewhere right?

When building software, it's a good idea to spend time up front writing out a specification for your project: what it will do, what it will look like, and what it should have. Remember that if you don't know what you're building, how will you ever know if it's done?

Listing out the requirements

We already know what we want our application to do, take notes. The problem is that there are so many ways that you could build a note-taking app that it's essential to sketch out just what we want ours to do. Not too much, not too little, but just enough, for now. It's a point of fact with developers that our applications are never "done", they're only finished "for now". With Notekeeper, we've decided that we want to be able to do the following three things with our application:

- Add a note
- Display a list of notes
- View a note/delete a note

After deciding what tasks our app needs to accomplish, we need to decide how it will accomplish them. The easiest approach is to simply write those things out in a list. By breaking each part down into smaller pieces we make it easier to understand, and to see just what we need to make it work. It's just like getting directions to your favourite restaurant; a left turn here, a roundabout there, and you're sitting down at the table before you know it. Let's look at each thing we want Notekeeper to do, with the pieces and parts underneath:

- Adding a note (form)
 - A form container. All user input widgets are wrapped up into a form.
 - A title, the name of the note. This will also be used to display existing notes.
 - The note itself. The content or body of the note.
 - A save button. This triggers the actual saving.

- The ability to display a list of notes (listview)
 - A row item containing the title of the note. This row should be a link to a page containing the body of the note.
 - A section header row might be nice.
- The ability to view a note, and delete a note (label, paragraph, button)
 - A label for the title of the note
 - A paragraph containing the content of the note
 - A button labeled **Delete**
 - A back button

Building your wireframes

Now that we've listed out the functionality for our app, how about we sketch each piece so that we get an idea of what we want it to look like? Don't worry if you failed art, or if you can't draw a stick figure. Use a ruler if you have to, or consider using Microsoft Excel, or PowerPoint if you have those. You just need to be able to draw some boxes and some text labels.

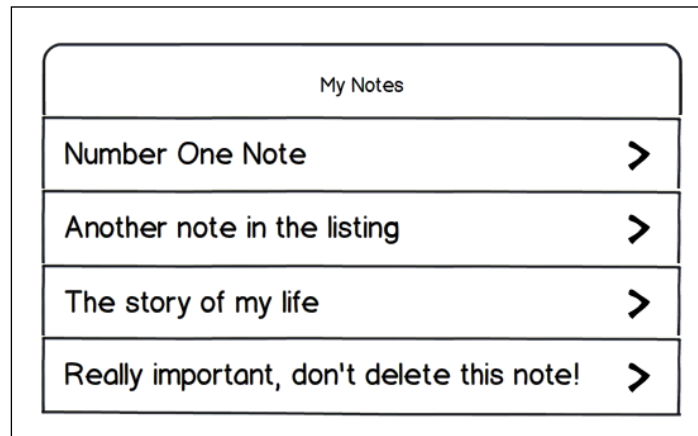

Designing the add note wireframe

Now, what about the add note part? We decided that it needs a title, a box for the note, and a submit button. The form is an invisible container so we don't need to draw that:

```
graph TD
    subgraph Form
        Title[Note Title]
        Content[Note Content]
        Button[Add Note]
    end
```

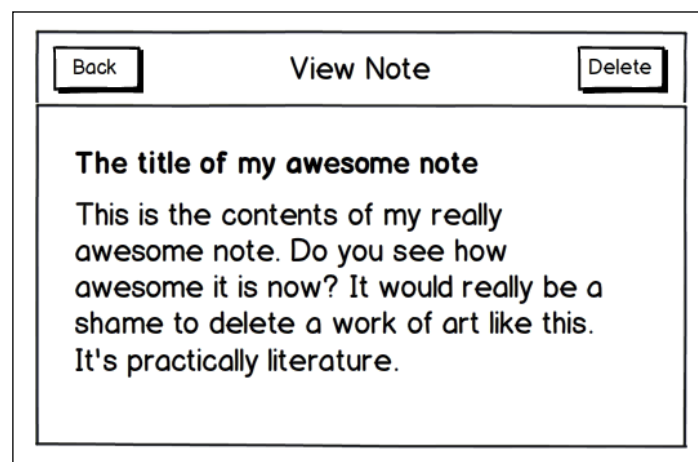

Display notes wireframe

The listview is an integral part of mobile development. It's the simplest way to group similar items together, plus it offers lots of extra functionality such as scrolling, and built in images for links. We'll be using a listview to display our list of notes:

View note/delete button wireframe

Finally, once we've added a note, we need to be able delete the evidence, I mean clear out old notes to make way for new ones. Note that we've also sketched out a back button. Once you start seeing things laid out, you'll find that you've forgotten something really important (like being able to return to the previous page):

Writing the HTML

Now that our wireframes are done, and we're happy with them it's time to turn pencil drawings into 1's and 0's. Since our app is relatively simple, none of the HTML should be difficult. You're more than halfway through the book after all and you should be doing these things in your sleep.

The HTML that you come up with should look remarkably like what's shown in the following code snippet. Let's examine it together:

Listing 10-1: notekeeper.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Notekeeper</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="http://code.jquery.com/mobile/
      latest/jquery.mobile.min.css" />
    <script src="http://code.jquery.com/jquery-1.6.4.js"></script>
    <script src="http://code.jquery.com/mobile/latest/
      jquery.mobile.min.js"></script>
    <script src="application.js"></script>
  </head>
  <body>
    <div data-role="page">
      <div data-role="header">
        <h1>Notekeeper</h1>
      </div>
      <div data-role="content">
        <form>
          <div>
            <input id="title" type="text" placeholder="Add a note" />
          </div>
          <div>
            <textarea id="note" placeholder="The content of your
              note"></textarea>
          </div>
          <div class="ui-grid-a">
            <div class="ui-block-a">
              <input id="btnNoThanks" type="submit" value="No Thanks" />
            </div>
            <div class="ui-block-b">
```

```
        <input id="btnAddNote" type="button" value="Add Note" />
      </div>
    </div>
  </form>
  <ul id="notesList" data-role="listview" data-inset="true">
    <li data-role="list-divider">Your Notes</li>
    <li id="noNotes">You have no notes</li>
  </ul>
</div>
<div data-role="footer" class="footer-docs">
  <h5>Intro to jQuery Mobile</h5>
</div>
</div>
</body>
</html>
```

Our Notekeeper application will make use of a single HTML file (notekeeper.html) and a single JavaScript file (application.js). Up until this point none of the code you've written has really needed JavaScript, but once you begin writing more complex applications, JavaScript will be a necessity. Preview the HTML from Listing 10-1 in your web browser and you should see something similar to the following screenshot:

Notice that we're displaying the **Add Note** form on the same page as the view notes. With mobile application development, it's a good idea to condense things where possible. Don't make this a hard and fast rule but since there's so little to our app, it's an acceptable decision to place both parts together as long as they're clearly labeled. You can see that this page meets all the requirements we set for adding a note, and for displaying our existing notes. It has a title input field, a note input field, a save button, and the entire thing is wrapped inside a form container. It also has a listview that will be used to display our notes once we start adding them. What isn't seen here is a delete button, but that will show up once we add our first note and view the details page.

Adding functionality with JavaScript

As this book has mentioned, you don't need to write any JavaScript to get your money's worth from jQuery Mobile. But as you begin to progress in your experience with jQuery Mobile you'll begin to see how much additional value JavaScript can add to your projects. Before we look at the code, let's talk about how it will be structured. If you've done any web design or development at all, you've probably seen JavaScript. It has been around since 1995 after all. The problem is that there's been many different ways to do the same thing in JavaScript and not all of them good.

The JavaScript code in this application will use what's called a design pattern. It's just a fancy term that specifies a certain structure to the code. There are three main reasons for using an existing design pattern:

- It helps our code stay organized and tidy.
- It prevents the variables and functions we write from being accidentally overwritten or altered by any other code we might add. A jQuery plugin perhaps, or code that's being loaded in from a third party website.
- It will help the future developers to acclimatize themselves to your code much more rapidly. You are thinking about future developers as you work on the next Facebook right?

Let's take a look at a very simple implementation of this design pattern before jumping into the full code:

```
Listing 10-2: kittyDressUp.js
$(document).ready(function() {
  // define the application name
  var kittyDressUp = {};
  (function(app) {
```

```
// set a few variables which can be used within the app
var appName = 'Kitty Dress Up';
var version = '1.0';
app.init = function(){
    // init is the typical name that developers give for the
    // code that runs when an application first loads
    // use whatever word you prefer
    var colors = app.colors();
}
app.colors = function(){
    var colors = ['red', 'blue', 'yellow', 'purple'];
    return colors;
}
app.init();
})(kittyDressUp);
});
```

If you're familiar with JavaScript or jQuery, you'll probably see some elements that you're familiar with. For those readers who aren't familiar with jQuery, or JavaScript we'll review this example line by line. `KittyDressUp.js` starts off with jQuery's best friend. Any code contained within the curly braces waits to execute until the document, or the HTML page, is completely loaded. This means that you, the developer, can be assured that everything which needs to be on the page is there before your code runs:

```
$(document).ready({
    // I'm ready captain!
});
```

In simple terms, the next line creates a variable named `kittyDressUp` and assigns it a value of an empty object. However, in our code this new object will contain our entire application:

```
// define the application name
var kittyDressUp = {};
```

The following declaration is the core of the Kitty Dress Up application. It creates a function that accepts a single argument, and then immediately calls itself, passing in the empty object we created in the previous line. This concept is known as a self-executing function and is what keeps the external code from interfering with our application.

```
(function(app){  
  // define the app functionality  
})(kittyDressUp);
```

The next two lines set a few variables that can only be accessed from within the context, or scope, of our application:

```
// set a few variables which can be used within the app  
var appName = 'Kitty Dress Up';  
var version = '1.0';
```

Finally, the last few lines set up two functions that are available for use within the application. You can see that each function is assigned a name that is within the scope of the larger application. The `app` variable is where the function lives, and the word after the `.` is the function name. Notice that within the `init` function we're calling another function inside the same application, `app.colors()`. We could also reference any of the variables that we defined at the top as well.

```
app.init = function(){  
  // init is the typical name that developers give for the  
  // code that runs when an application first loads  
  // use whatever word you prefer  
  var colors = app.colors();  
}  
app.colors = function(){  
  var colors = ['red', 'blue', 'yellow', 'purple'];  
  return colors;  
}  
app.init();
```

Remember that `app` was the name of the parameter passed into the self-executing function, and that its value is an empty object. Taken as a whole these few lines create an object named `kittyDressUp` that contains two variables (`appName` and `version`), and two functions (`init` and `colors`). This example, as well as the code for `Notekeeper`, are simple examples, but they illustrate how you can go about wrapping up code for various pieces of a larger app into discrete packages. In fact, after `kittyDressUp.js` runs you could even pass the `kittyDressUp` into yet another set of code for use there.

Phew...everyone take five, you've earned it.

Storing Notekeeper data

Now that we're back from our five minute break it's time to roll up our sleeves and get to work adding functionality to our app. While we've talked about how we want Notekeeper to behave, we haven't discussed the core issue of where to store the note data. There are a few possibilities, all of which have pros and cons. Let's list them out:

- **Database (MySQL, SQL Server, PostgreSQL):** While a database would be the ideal solution, it's a little complex for our app, it requires internet connectivity, and you'd need a server-side component (ColdFusion, PHP, .NET) acting as a middle man to save notes to the database.
- **Text file:** Text files are great because they take up very little room. The problem is that as a web app, Notekeeper can't save files to the user's device.
- **localStorage:** localStorage is relatively new, but it's quickly becoming a good option. It stores information on the user's machine in key/value pairs. It's got a size limit, but it's pretty large for plain text, most modern browsers support it, and it can be used in offline mode.

Using localStorage

For the purposes of this chapter, we'll be selecting localStorage as our method of choice. Let's take a quick look at how it behaves so that you'll be familiar with it when you see it. As mentioned earlier, localStorage works on the premise of storing data in key/value pairs. Saving a value to localStorage works in one of two ways and is easy, no matter which one you choose:

```
localStorage.setItem('keyname', 'this is the value I am saving');
```

or

```
localStorage['keyname'] = 'this is the value I am saving';
```

Which version you choose is personal preference, but because it's slightly less typing we'll be using the second method, square brackets. One issue we'll run into is that localStorage can't store complex data like arrays, or objects. It only stores strings. That's a problem because we're going to be storing all of our data inside one variable so that we always know where it lives. Never fear, we can pull a fast one on localStorage and convert our complex object into a string representation of itself using a built in function called `stringify()`.

The following code snippet shows how it works:

```
// create our notes object
var notes = {
  'note number one': 'this is the contents of note number one', 'make
    conference call': 'call Evan today'
}
// convert it to a string, then store it.
localStorage['Notekeeper'] = JSON.stringify(Notekeeper);
```

Retrieving a value is just as simple as setting it, and it also offers two options. You'll usually want to define a variable to receive the contents of the `localStorage` variable.

```
var family = localStorage.getItem('my family');
or
```

```
var family = localStorage['my family'];
```

If you're retrieving a complex value there's an additional step that must be performed before you can use the contents of the variable. As we just mentioned, to store complex values you must first use the `stringify()` function, which has a counterpart function called `parse()`. The `parse()` function takes the string containing that complex object and turns it back into pure JavaScript. It's used as follows:

```
var myFamily = ['andy', 'jaime', 'noelle', 'evan', 'mason'];
localStorage['family'] = JSON.stringify(myFamily);
var getFamily =JSON.parse(localStorage['family']);
```

Finally, if ever you wanted to delete the key completely then you can accomplish it in a single line of code, again with two flavors:

```
localStorage.removeItem('my family');
or
```

```
delete localStorage[my family];
```

It's worth noting that if you try to retrieve a key that doesn't exist within `localStorage`, JavaScript won't throw an error. It'll just return "undefined" which is JavaScript's way of saying "sorry, but nothing's there". The following code snippet is an example:

```
var missing = localStorage['yertl the turtle'];
console.log(missing);
// returns undefined
```

Effective use of boilerplates

One last thing before we start building our JavaScript file. In our application, we're only going to have one JavaScript file, and it's going to contain the entire codebase. This is fine for smaller apps like ours, but it's a bad idea for larger apps. It's better to break up your project into distinct pieces, then put each of those into their own files. This makes it easier for teams of developers to work together (for example, Noelle works on the login process, while Mason builds out the list of vendors). It also makes each file smaller and easier to understand because it only addresses one part of the whole. When you want all of the pieces of your app to have a similar structure and design, it's a good idea to start each section with a boilerplate. We'll be using a boilerplate for our app's only file (which you can see in the following code snippet, Listing 10-3). You might notice it looks very similar to the `kittyDressUp` example, and you'd be right:

```
Listing 10-3: application.js
$(function() {
  // define the application
  var Notekeeper = {};
  (function(app) {
    // variable definitions go here
    app.init = function() {
      // stuff in here runs first
    }
    app.init();
  })(Notekeeper);
});
```

Building the Add Note feature

At last, we can get started building! Since it's difficult to display a list of notes that don't exist, much less delete one, we'll start writing the `Add Note` functionality first. For a user to be able to add a note, they have to enter a title, the contents of a note, then hit the submit button. So let's start there.

Adding bindings

We're going to create a new, empty, function block under the `app.init()` function definition. It should look something similar to the following line of code:

```
app.bindings = function() {
}
```

The bindings function will contain any piece of code that needs to fire when a user does something in our app, like clicking the submit button or the delete button. We group that code together for the sake of organization. Within the `bindings()` function we're going to add the following lines. This will fire when a user clicks the submit button on the Add Note form:

```
// set up binding for form
$('#btnAddNote').bind('click', function(e) {
    e.preventDefault();
    // save the note
    app.addNote(
        $('#title').val(),
        $('#note').val()
    );
});
```

jQuery's `val()` function is a shorthand method used to get the current value of any form input field.

A few notes about this new addition:

- When using jQuery, there will always be more than one way to accomplish something, and in most cases you simply pick the one that you like the best (they usually offer identical performance). You might be more familiar with `$('#btnAddNote').click()` and that's just fine as well.
- Notice that the `click` function accepts a single parameter: `e` which is the event object (in this case a click event). We call `e.preventDefault()` to stop the standard click event from happening on this element, but still allow the remaining code to continue running. You might have seen other developers use `return false`, but jQuery best practices recommend using `e.preventDefault()` instead.
- Within the click binding, we're calling the `addNote` function, and passing into it the title typed in by the user, and the note. The whitespace is unimportant, serving merely to make it easier to see what we're doing.

Even though we've added the binding to our code, if you run the app right now, nothing will happen when you click the **Add Note** button. The reason is that nothing has actually called the `bindings()` function yet. Add the following line inside the `init()` function and you'll be ready to go:

```
app.init = function() {
    app.bindings();
}
```

Collecting and storing the data

Next we add another new, empty, function block under `app.bindings`:

```
app.addNote = function(title, note){  
  }  
}
```

Now, because we're storing all of our notes into one key within `localStorage`, we first need to check to see if any notes already exist. Retrieve the Notekeeper key from `localStorage`, save it to a variable, then compare it. If the value of the key we ask for is an empty string, or undefined we'll need to create an empty object. If there is a value, then we take that and use the `parse()` function to turn it into JavaScript:

```
var notes = localStorage['Notekeeper'];  
if (notes == undefined || notes == '') {  
  var notesObj = {};  
} else {  
  var notesObj = JSON.parse(notes)  
}
```

Notice that we're expecting two variables to be passed into the `addNote()` function, `title` and `note`. Next we replace any spaces in the title with dashes, this makes it easier for some browsers to understand the string of text. Then we place the key/value pair into our newly minted notes object:

```
notesObj[title.replace(/ /g, '-')] = note;
```

The JavaScript `replace` method makes string manipulation quite simple. It acts on a string, taking a search term and a replacement term. The search term can be a simple string, or a complex regular expression.

The next step is to take our `notesObj` variable, `stringify()` it and place it into `localStorage`. We then clear the values from the two input fields to make it easier for the user to input another note. As a rule in building software it's a nice touch to return the interface to its original state after an action such as adding or removing content:

```
localStorage['Notekeeper'] = JSON.stringify(notesObj);  
// clear the two form fields  
$note.val('');  
$title.val('');  
//update the listview  
app.displayNotes();
```

All of these variable definitions should be familiar to you with perhaps one exception that we should point out. Many jQuery developers like to use conventional naming for variables which contain jQuery objects.

Specifically, they prepend the variable name with a `$` sign just like with jQuery. This lets them, or future developers know, what's contained within the variable. Let's go ahead and add those definitions to the top of our app. Just after the line which reads `// variable definitions go here`, add the following lines. They refer to the title input field and the note textarea field respectively:

```
var $title = $('#title');  
var $note = $('#note');
```

As a final step to this function we fire off a call to `app.displayNotes()` to update the list of notes. Since that function doesn't exist yet, let's create it next.

Building the Display Notes feature

You probably tested out the `Add Note` feature while writing the previous section. This means that you'll have at least one note saved in `localStorage` for use in testing the `Display Notes` feature. By now you're familiar with our first steps for any new section. Go ahead and add your empty `displayNotes()` function to hold our code:

```
app.displayNotes = function(){  
}
```

Next we need to retrieve all of our notes from `localStorage`:

```
// get notes  
var notes = localStorage['Notekeeper'];  
// convert notes from string to object  
return JSON.parse(notes);
```

You might start to see a pattern with many of our functions, almost all of them begin with us retrieving notes from `localStorage`. While there are only two lines of code needed to perform this task, there's no need for us to repeat those two lines each time we need to get the notes. So we're going to write a quick helper function containing those two lines. It looks similar to the following code snippet:

```
app.getNotes = function(){  
  // get notes  
  var notes = localStorage['Notekeeper'];  
  // convert notes from string to object  
  return JSON.parse(notes);  
}
```

With our new helper function in place, we can use it in the `displayNotes()` function as shown in the following code snippet:

```
app.displayNotes = function(){
  // get notes
  var notesObj = app.getNotes();
}
```

Now that we have the `notesObj` variable containing our packet of notes, we need to loop over that packet and output the contents:

```
// create an empty string to contain html
var html = '';
// loop over notes
for (n in notesObj) {
  html += li.replace(/ID/g,n.replace(/-/g,' ')).replace(/LINK/g,n);
}
$ul.html(notesHdr + html).listview('refresh');
```

It might seem odd for the line inside the `for` loop to have multiple `replace` statements, but the nature of JavaScript allows for methods to be chained. Chaining refers to a method which returns the entire results of its action. Adding an additional method call simply repeats the process.

There might be some new concepts in this code block so let's take a closer look. The variable named `html` is nothing special, but how we're using it might be. As we loop over the existing notes, we're storing new information into the `html` variable along with whatever else is inside it. We accomplish this by using the `+=` operator which allows us to assign and append at the same time.

The second thing you might notice is the `li` on the right side of the assignment. Where does that come from? That's a template for a single list item which has not yet been created. Let's do that right before we talk about it. At the top of your `app.js` file, just after the line which reads `// variable definitions go here`, add the following two lines of code:

```
var $ul = $('#notesList');
var li = '<li><a href="#pgNotesDetail?title=LINK">ID</a></li>';
```

You should already be familiar with the convention of adding a `$` before a variable to indicate a jQuery object. That's what we're doing with the `$ul` variable. The second variable, the `li` is slightly different. This contains the HTML for a single list item that will display a notes title. It's best practice to avoid mixing HTML or CSS in with your JavaScript wherever possible. We're declaring this as a template now in case we decide to use it in multiple places later.

The other part which might be of interest is the way we're using the `li` variable. When calling the string replace function, we're looking for all occurrences of the word LINK (upper case intended) and replacing it with the title of the note. Because JavaScript is a case-sensitive language it's a safe assumption that we won't run into a natural occurrence of that work.

Dynamically adding notes to our listview

There's one final thing we need to put in place before our notes show up on the page. You might have noticed that the only place which calls the `displayNotes()` function appears within the `addNote()` function. This is a good place for it, but it can't be the only place. We need something that runs when the page first loads. The prime place for this would be in the `init()` function, and that's where we'll place it.

There's one problem though, we can't just load our notes and run, what happens if there are no notes? We need a nice message to display to the user so that they don't think something's wrong. Let's create a new function called `app.checkForStorage()` which handles all of this:

```
app.checkForStorage = function(){
  // are there existing notes?
  if (localStorage['Notekeeper']) {
    // yes there are. pass them off to be displayed
    app.displayNotes();
  } else {
    // nope, just show the placeholder
    $ul.html(notesHdr + noNotes).listview('refresh');
  }
}
```

By now, all of this should be familiar to you: checking `localStorage` for notes, and calling the `displayNotes()` function if it finds them. The second part has some new items though. When we set the html for the `$ul` jQuery object, we're calling two new variables. One for the listview header, and another if we don't have any notes. Let's add those two variable definitions now. Under `// variable definitions` go here, add the following two lines:

```
var notesHdr = '<li data-role="list-divider">Your Notes</li>';
var noNotes = '<li id="noNotes">You have no notes</li>';
```

The last part of the line normally might go unnoticed, but we won't let it. It's really crucial. jQuery Mobile offers developers options. The option of having static HTML code, that's already on the page when it loads; jQuery Mobile also provides an option for adding HTML code on the fly. That really gives developers lots of flexibility, but it presents a unique challenge as well. By design jQuery Mobile converts HTML into stylish looking buttons before the page loads. This means that any HTML added after that will be presented to the user without any style.

However, jQuery Mobile also offers a way to get around this by building in the ability to refresh each and every element that it converts. Most of them have a built-in function corresponding to the name of the element; in our case it's the `listview()` function. Actually this method offers the ability to add a completely new listview to the page. In our situation we only care about refreshing the one we have, so we simply add the `refresh` keyword and jQuery Mobile converts your plain text listview. Try leaving that last part off and see just how much work jQuery Mobile saves you. Maybe you should add the jQuery Mobile team to your Christmas card list?

Finally, we have to actually call our newest function. Within the `init()` function add the following line. Then reload the page and watch your notes load up.

```
app.checkForStorage();
```

Viewing a note

At this point we should be able to create a new note, and have that note be immediately displayed in our listview. In fact, the rows in the listview are already links, they just don't work, let's change that right now.

Using the Live function

Add the following lines to the `bindings()` function:

```
$('#notesList a').live('click',function(e){
    e.preventDefault();
    var href = $(this)[0].href.match(/\?.*$/)[0];
    var title = href.replace(/^\?title=/, '');
    app.loadNote(title);
});
```

This new binding has a few new concepts so let's unpack them. First up, we're not using the `bind` function, instead we use jQuery's `live` function. The difference is that `bind` only works on existing page elements, whereas `live` is proactive. It works on existing elements as well as ones which get created after the binding is applied.

The second and third lines of the binding might look a little confusing but they only do one thing. They retrieve the URL from the href attribute of the link that was clicked. The `li` template we defined earlier in the chapter contained the following URL for each list item:

```
#pgNotesDetail?title=LINK
```

After the `displayNote()` function runs, the URL looks like this (run your mouse over each list item to see the link displayed at the bottom of your browser window):

```
#pgNotesDetail?title=the-title-of-the-note
```

Finally we tell our code to run a new function appropriately named `app.loadNote()`.

Dynamically creating a new page

If you haven't already created the new empty function block for our new `loadNote()` function, go ahead and do it now. Remember that we're passing in the title of the note we want to view, so make sure to add that as an argument in the `loadNote()` function:

```
app.loadNote = function(title) {
}
```

Then place the following two lines at the top of the function:

```
// get notes
var notes = app.getNotes();
// lookup specific note
var note = notes[title];
```

The first line retrieves our note object, while the second line pulls the specific note that the user has requested. The next variable definition breaks the rule we mentioned earlier in the chapter about mixing HTML and JavaScript, but every rule has exceptions. We're defining it here as opposed to the header of our JS file since this is the only place it is needed. This still serves the purpose of keeping the document organized.

```
var page = '<div data-role="page" data-url="details" data-add-back-
  btn="true">\
  <div data-role="header">\
    <h1>Notekeeper</h1>\
    <a id="btnDelete" href="" data-href="#ID" data-role="button"
      class="ui-btn-right">Delete</a>\
  </div>\
  <div data-role="content"><h3>TITLE</h3><p>NOTE</p></div>\
</div>';
```

The page variable now contains all of the HTML needed to display a "note details" page to the user. Do you recall that our app has only one HTML file? We're actually creating an entire page from scratch using the previous HTML code. There are also some details in it worth pointing out:

- By default jQuery Mobile does not offer a back button for pages. You can, however, enable one on a page by page basis using the `data-add-back-btn="true"` attribute on any `div` tag which also has a `data-role="page"` attribute.
- The `data-url` attribute is an identifier used by jQuery Mobile so that it can keep track of multiple pages which are generated.

Now that we have a whole page contained within a variable, what can we do with it? The first thing we can do is to turn it into a jQuery object. By wrapping any distinct chunk of HTML with a `$()` you turn it into a Grade-A jQuery object:

```
var newPage = $(page);
```

Then we can take the HTML of that newly created page and replace parts of it with the values from our selected note.

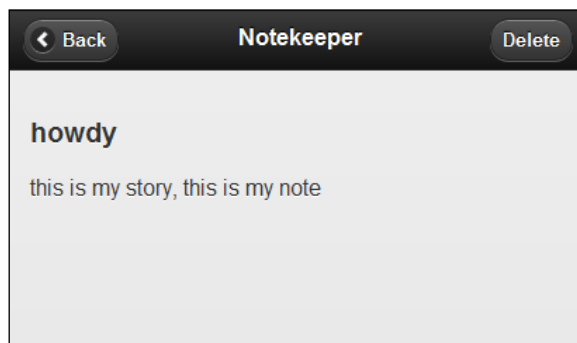

```
//append it to the page container
newPage.html(function(index,old) {
    return old
        .replace(/ID/g,title)
        .replace(/TITLE/g,title)
        .replace(/-/g,' ')
        .replace(/NOTE/g,note)
    }).appendTo($.mobile.pageContainer);
```

Since Version 1.4, jQuery has offered the option of a **callback** within certain functions. These include `.html()`, `.text()`, `.css()` and a few others. This function expects two arguments, of which the second contains the full HTML currently contained within the matching element. This means that we can make tweaks to the HTML contained inside our `newPage` variable without having to completely change it. Wonderful isn't it?

Next we're appending the entire `newPage` variable to the end of the current page, referenced here by the `$.mobile.pageContainer` constant. Finally, because we cancelled the default click action in our binding, we have to tell the link to perform an action which is to forward the user to this newly created page. jQuery Mobile offers a built-in way to do this:

```
$.mobile.changePage(newPage);
```

And now for the grand reveal. If you load up `notekeeper.html` in your browser you should be able to add, display, and finally view notes, all within the confines of a single browser window. Isn't jQuery Mobile great?

Deleting a note

Looking back to the requirements for our app, we're doing pretty well. We've written HTML code that sets up the document structure, allowed us to add a note, display notes, and view a note. All that's left is deleting a note and it begins with a last binding set up in our `bindings()` function. Let's add it right now:

```
$('#btnDelete').live('click',function(e) {
    e.preventDefault();
    var key = $(this).data('href');
    app.deleteNote(key);
});
```

There's only one item that might be new to you in this binding, the use of jQuery's `.data()` function. HTML 5 allows you to store arbitrary data directly on any HTML element by using an attribute prepended with `data-` and this ability is at the core of jQuery Mobile's functionality. Anywhere you see `data-role="something"`, you're seeing HTML 5 data in action. Further jQuery allows you to retrieve any `data-` value by using the `.data()` function and passing in the key of the item you want to view. In the case above we've stored the title of the note into a `data-href` attribute directly on the delete button within the view page. Because the binding we're adding is a click handler assigned to the delete button we can retrieve the title of the note by calling `$(this).data('href')`. Neat-o!

This will be the last function that we add in this chapter. Are you sad? It's a poignant moment for certain, but we can look back on this with fondness after you're a successful jQuery Mobile developer. Once again we start with an empty function which accepts a single argument, the title of the note we're deleting.

```
app.deleteNote = function(key) {  
}
```

Follow the function definition up with our helper function for retrieving notes:

```
// get the notes from localStorage  
var notesObj = app.getNotes();
```

Then we delete the note. You've already seen this in action when we reviewed `localStorage` so it should be familiar to you:

```
// delete selected note  
delete notesObj[key];  
// write it back to localStorage  
localStorage['Notekeeper'] = JSON.stringify(notesObj);
```

Deleting the note is followed in quick succession by writing the remaining notes back to `localStorage`. The final two lines in the `deleteNote()` function take us back to the main page of the app, the list of notes. They also trigger the original `checkForStorage()` function.

```
// return to the list of notes  
$.mobile.changePage('notekeeper.html');  
// restart the storage check  
app.checkForStorage();
```

The last line may seem odd to you, but keep in mind that we don't know in advance if there are still any notes left. Running through the storage check allows us to display the placeholder text, in case there are no notes. It's a good habit to get into, as it helps our app become less prone to errors.

Summary

In this chapter, we built a living, breathing mobile application with jQuery Mobile. Stop and give yourself a pat on the back. We walked through the process of listing the requirements for our app, building the wireframes, and writing the HTML. We learned about HTML 5's `localStorage`, using templates for text replacement, and some of the cooler features of jQuery Mobile including dynamically adding and refreshing elements on the page.

In the next chapter, you'll learn how to set global configuration options for jQuery Mobile, how to use other APIs within jQuery Mobile to work with forms and content blocks.

11

Enhancing jQuery Mobile

In this chapter, we'll learn how to enhance jQuery Mobile, how to make your mobile applications really stand out from the pack by creating themes and icons to improve the look and functionality of our app.

In this chapter, we will:

- Learn about the building blocks of jQuery Mobile
- Create our own jQuery Mobile theme using ThemeRoller
- Design and implement custom icons for our application

What's possible?

The reaction many developers have when using jQuery Mobile for the first time is awe at how easy it is to implement a rich, compelling mobile website for their users. The ease with which it converts plain HTML to beautiful, usable buttons, and listviews. The form elements are a dream to work with. The jQuery Mobile team even shipped five well designed and attractive themes and 18 commonly used icons along with the rest of the package. They even built a tool that we can use to build our own themes; **ThemeRoller**.

After working with jQuery Mobile for sometime developers might be asking "*what else can I do with this?*" Just like muscle cars from the 60s and 70s. It wasn't enough that they were already awesome, the tweekers and the gearheads wanted to do more. If you are identified with that mentality then this chapter is for you.

The wonderful thing about jQuery Mobile is that because it's all plain CSS and HTML, we can do almost anything we want to it with very little effort. In this chapter we'll be creating our own theme from scratch using ThemeRoller for jQuery Mobile. We'll be designing buttons and writing the CSS code needed to implement both low and high resolution versions. We'll also be looking at how we can expand on the styles and classes already available in jQuery Mobile and make something different and unique. Let's get started now, shall we?

The visual building blocks of jQuery Mobile

As you've already seen, jQuery Mobile is very user friendly and pleasing to the eye. It makes good use of rounded corners, subtle gradients, drop shadows to make elements stand out from their surroundings, and other *tricks* that graphic designers have been using for years in print. But on the web, these effects were only possible with the use of images, or complicated and poorly supported plugins and applets.

With the advent of the Web 2.0 and CSS 3, all of these options have been made available to us, the layman web developers. Just remember that with great power comes great responsibility. jQuery Mobile operates on the principle of progressive enhancement. A tricky phrase but it just means that you should develop for the lowest common denominator and offer enhancements for browsers that understand them.

Luckily for us these stylistic additions are almost purely cosmetic. If a browser doesn't understand the `border-radius` declaration, then it simply displays squared off corners. The same holds true for gradients and shadows. While jQuery Mobile adds these effects to your application out of the box, it's worthwhile knowing how to add them on your own.

Border-radius

Rounded corners can be one of the most elegant and appealing effects, and they are also the simplest to add. There are a few caveats that developers need to know about this effect and the other effects. While there is a specification for `border-radius` as recommended by the W3C, it turns out that each of the primary browser manufacturers supports it in slightly different ways. The end result is the same, but the path to it varies. Let's take a look at the most basic `border-radius` declaration, and the following screenshot is its result:

```
#rounded {  
    border-radius: 10px;  
}
```

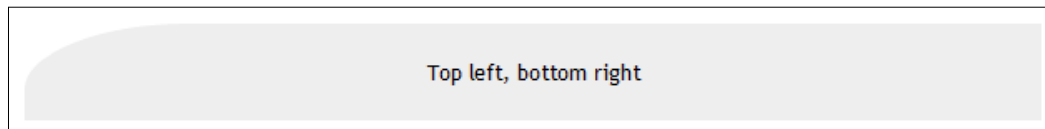

You also have the option of rounding only certain corners, as well as tweaking the values so that the corner isn't a perfect quarter-circle. Let's look at a few more examples. The following code snippet and the screenshot demonstrate an example to get two rounded corners:

```
#topLeftBottomRight {  
    border-radius: 15px 0 15px 0;  
}
```

The following code snippet and the screenshot demonstrate an example to get one rounded corner:

```
#bottomLeft {  
    border-top-left-radius: 100px 40px;  
}
```

Sadly, it's not quite as easy as this, just yet. Because each browser vendor has their own unique rendering for this effect, software developers like Google, or Mozilla have taken to creating their own versions, commonly called **vendor prefixes**. For the previous style declarations to have the widest range of coverage you'd have to add the following lines of code:

```
#rounded {
  -webkit-border-radius: 10px;
  -moz-border-radius: 10px;
  border-radius: 10px;
}
#topLeftBottomRight {
  -webkit-border-top-left-radius: 15px;
  -webkit-border-bottom-right-radius: 15px;
  -moz-border-radius-topleft: 15px;
  -moz-border-radius-bottomright: 15px;
  border-top-left-radius: 15px;
  border-bottom-right-radius: 15px;
  /* mozilla and webkit prefixes require you to define each corner
     individually when setting different values */
}
#bottomLeft {
  -webkit-border-top-left-radius: 100px 40px;
  -moz-border-radius-topleft: 100px 40px;
  border-top-left-radius: 100px 40px;
}
```

Applying drop shadows

Drop shadows in CSS take one of two forms: text-shadows (applied to text) and box-shadows (applied to everything else). Like border-radius, drop shadows are fairly straightforward if you're looking at the W3C specification.

Using text-shadow

Let's look at `text-shadow` first:

```
p {  
  text-shadow: 2px 2px 2px #000000;  
  /* horizontal, vertical, blur, color */  
}
```

The text in this paragraph will have a drop shadow that is offset 2 pixels to the right, 2 pixels to the bottom, is blurred by 2 pixels, and whose color is black.

This property also supports multiple shadows by adding additional declarations in a comma separated list, as shown in the following code snippet and the output:

```
p {  
  text-shadow: 0px 0 px 4px white,  
    0 px -5px 4px #ffff33,  
    2px -10px 6px #ffdd33,  
    -2px -15px 11px #ff8800,  
    2px -25px 18px #ff2200  
}
```

How about a cheesy fire effect!

Unlike the `border-radius` property, the `text-shadow` property doesn't require vendor prefixes. That doesn't mean that all browsers support it, it simply means that browsers that do support this property, display it as intended, while browsers that do not, simply see nothing.

Using box-shadow

Box-shadow follows a very similar model to text-shadow, with one addition, that is the `inset` keyword which allows for inner shadowing. Let's get to the examples. The first example shows standard outer shadows:

```
#A {
  -moz-box-shadow: -5px -5px #888888;
  -webkit-box-shadow: -5px -5px #888888;
  box-shadow: -5px -5px #888888; /* horizontal, vertical, color */
}
#B {
  -moz-box-shadow: -5px -5px 5px #888888;
  -webkit-box-shadow: -5px -5px 5px #888888;
  box-shadow: -5px -5px 5px #888888;
  /* horizontal, vertical, blur, color */
}
#C {
  -moz-box-shadow: 0 0 5px 5px #888888;
  -webkit-box-shadow: 0 0 5px 5px #888888;
  box-shadow: 0 0 5px 5px #888888;
  /* horizontal, vertical, blur, spread, color */
}
```

And now, in the following example check out these inner shadows. Snazzy eh?

```
#D {
  -moz-box-shadow: inset -5px -5px #888888;
  -webkit-box-shadow: inset -5px -5px #888888;
  box-shadow: inset -5px -5px #888; }
#E {
  -moz-box-shadow: inset -5px -5px 5px #888888;
  -webkit-box-shadow: inset -5px -5px 5px #888888;
  box-shadow: inset 0px 0px 10px 20px #888888;
```

```

}
#F {
  -moz-box-shadow: inset -5px -5px 0 5px #888888;
  -webkit-box-shadow: inset -5px -5px 0 5px #888888;
  box-shadow: inset 0 0 5px 5px #888888;
}

```

It's worth mentioning that both box-shadow and text-shadow can have their colors set with the less commonly used `rgb` and `rgba` declarations. This allows the developers to set colors using the more familiar convention of RGB values. The `rgba` declaration also allows setting color opacity from 0 to 1. The code for that is a simple change, as shown in the following snippet:

```

#opacity {
  box-shadow: inset 0 0 5px 5px rgb(0,0,0); /* black */
}
#transparent {
  box-shadow: inset 0 0 5px 5px rgba(0,0,0,.5);
  /* black with 50% transparency */
}

```

CSS gradients

CSS gradients are a great way to add beauty and impact to your website. Options include linear gradients (right to left, top to bottom, and so on.), and radial gradients (from center outwards). By default, gradients consist of a start color and an end color. CSS gradients may also include additional tones using color stops.

It should be noted however that support for CSS gradients in older browsers isn't perfect, specifically in Internet Explorer. The good news is that there are ways to address IE that can allow developers to reliably use gradients in their development. The bad news is that the code for that support is *robust*. Let's take a look at the simplest possible gradient declaration:

```

div {
  width: 500px;
  height: 100px;
  background: linear-gradient(left, #ffffff 0%,#000000 100%);
}

```

Gradient declarations can be quite complex so let's break it down with an infographic:

Now here's the kicker...at the time of writing this, there were no browsers that supported the W3C specification using the actual property. Let's take a look at the code to support multiple browsers and you'll love jQuery Mobile even more than you already do:

```
div {
  width: 500px;
  height: 100px;
  border: 1px solid #000000;
  /* Old browsers */
  background: #ffffff;
  /* FF3.6+ */
  background: -moz-linear-gradient(left, #ffffff 0%, #000000 100%);
  /* Chrome10+,Safari5.1+ */
  background: -webkit-linear-gradient(left, #ffffff 0%,#000000 100%);
  /* Opera 11.10+ */
  background: -o-linear-gradient(left, #ffffff 0%,#000000 100%);
  /* IE10+ */
  background: -ms-linear-gradient(left, #ffffff 0%,#000000 100%);
  /* W3C spec*/
  background: linear-gradient(left, #ffffff 0%,#000000 100%);
  /* IE6-9 */
  filter: progid:DXImageTransform.Microsoft.gradient(
    startColorstr='#ffffff', endColorstr='#000000',GradientType=1 );
}
```

You can add multiple colors to your gradient by adding additional comma separated declarations. For example, the following code:

```
div {
  width: 500px;
  height: 100px;
  border: 1px solid #000000;
  /* Old browsers */
  background: #ffffff;
  /* FF3.6+ */
  background: -moz-linear-gradient(left,  #ffffff 0%, #000000 35%,
    #a8a8a8 100%);
  /* Chrome10+,Safari5.1+ */
  background: -webkit-linear-gradient(left,  #ffffff 0%,#000000
    35%,#a8a8a8 100%);
  /* Opera 11.10+ */
  background: -o-linear-gradient(left,  #ffffff 0%,#000000 35%,#a8a8a8
    100%);
  /* IE10+ */
  background: -ms-linear-gradient(left,  #ffffff 0%,#000000
35%,#a8a8a8
    100%);
  /* W3C */
  background: linear-gradient(left,  #ffffff 0%,#000000 35%,#a8a8a8
    100%);
  /* IE6-9 */
  filter: progid:DXImageTransform.Microsoft.gradient(
    startColorstr='#ffffff', endColorstr='#a8a8a8',GradientType=1 );
}
```

Results are shown in the following gradient:

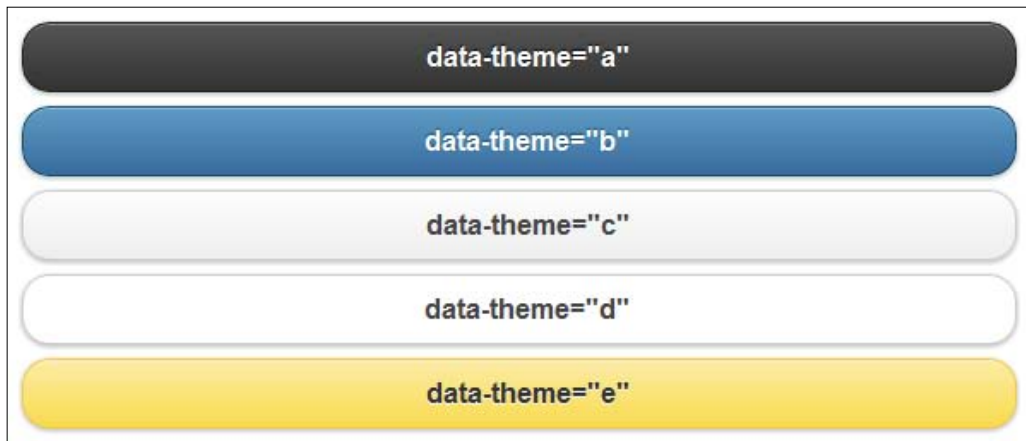

As you might guess after reading the last few pages, jQuery Mobile does a lot of heavy lifting on your behalf. Not only does it add slick gradient page backgrounds, but it has to keep track of all of the browser quirks that might prevent that sweet drop shadow from showing up. As we move into the next section you'll likely be even more impressed with the way it handles themes and color swatches.

The basics of jQuery Mobile theming

Theming in jQuery Mobile is straightforward and simple to use for the developer, but is pretty elaborate behind the scenes. Luckily there will rarely be a time when you need to know everything that's being done for you. However, it's worth a little bit of our time to understand how it works.

Out of the box jQuery Mobile comes with a theme set comprised of five color swatches, each associated with a letter from A-E. The theme contains a series of base CSS classes which can be applied at will to nearly any element and they contain global settings for width, height, border radius, shadows. The individual swatches contain specific information about color, fonts, and so on.

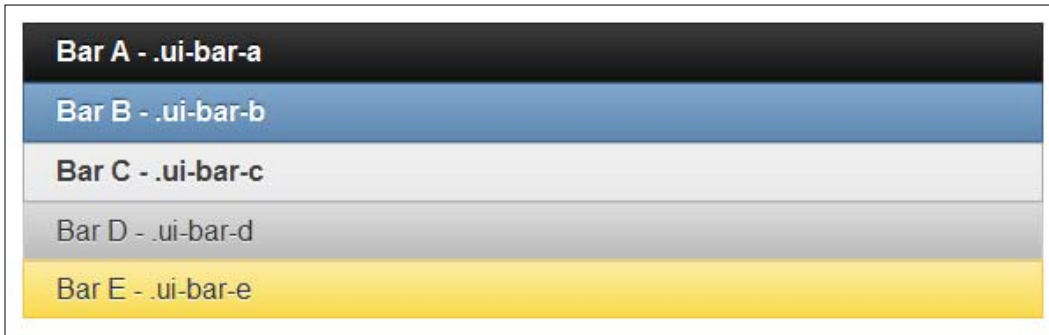

Additional swatches can be added to the five original swatches from F-Z, or the original swatches can be replaced or overridden at will. This system allows for a total of 26 distinct swatches, allowing for millions of possible combinations of theme colors, styles, and patterns. You apply a jQuery Mobile theme to the selected element by adding a `data-theme` attribute with the letter of the desired theme:

Developers will generally choose to use the `data-theme` attribute method when applying styles, but it's also possible to attach the CSS class names directly to your page elements for more granular control. There are a handful of primary prefixes which allow for this flexibility.

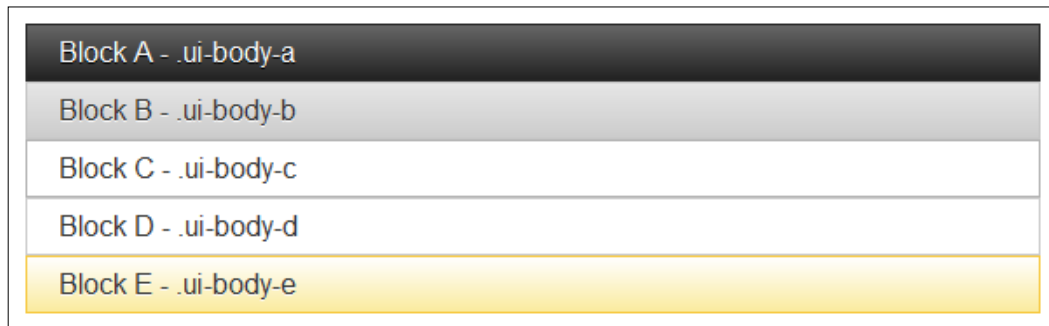

Bars (.ui-bar-?)

The bar prefix is generally applied to headers, footers, and other areas with high importance:

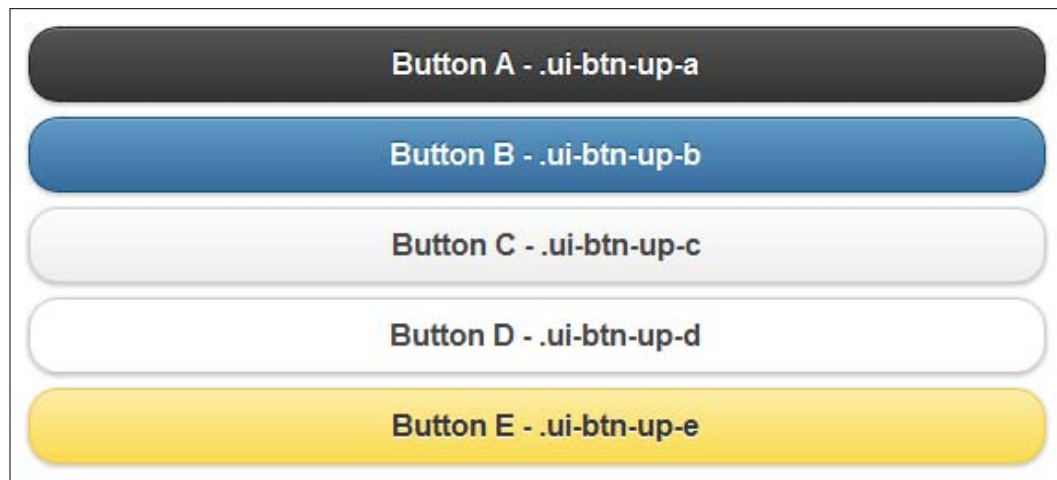

Content blocks (.ui-body-?)

Content blocks are generally applied to areas where paragraph text is expected to occur. Its color helps to ensure maximum readability with the text color placed against it:

Buttons and listviews (.ui-btn-?)

Buttons and listviews are two of the most important elements in the jQuery Mobile library and you can rest assured that the team took their time getting them right. The `.ui-btn` prefix also includes styles for up, down, hover, and active states:

Mixing and matching swatches

One of the nice things about theming in jQuery Mobile is that child elements inherit from their parent unless otherwise specified. This means that if you put a button without its own `data-theme` attribute inside a header or footer bar, that button will use the same theme as its parent. Wicked eh?

It's also perfectly acceptable, and even encouraged, to place an element using one swatch and the child of an element using another swatch. This can help the element stand out more, or match a different part of the app, or whatever reasoning the developer chooses. It's possible, and what's more it's easy. Simply place a button (or other element) inside a header bar, and assign it its own `data-theme` attribute:

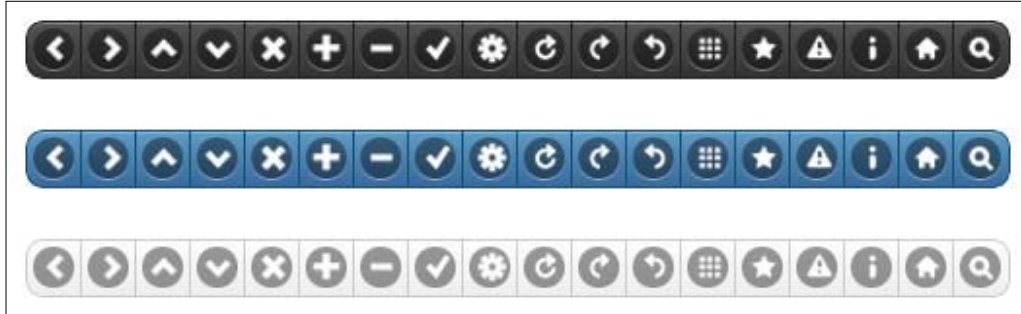

Site-wide active state

jQuery Mobile also applies a global *active* state for all elements. This active state is used for buttons, form elements, navigation, and anywhere there's a need to indicate that something is currently selected. The only way to change this color value is to set (or override) it via CSS. The CSS class for the active state is, appropriately named, `.ui-btn-active`:

Default icons

Included in the jQuery Mobile set are 18 icons which cover a wide array of needs for developers. The icon set is white on transparent which jQuery Mobile overlays over a semi-transparent black circle to provide contrast against all of the swatches. To add an icon, specify the `data-icon` attribute with the name of the desired icon:

jQuery Mobile also provides the ability to place icons on the top, right, bottom, or left side of a button using the `data-iconpos=" [top, right, bottom, left] "` attribute, with left being the default placement. Developers are also able to display an icon alone, without text, by specifying `data-iconpos="notext"`:

Deploying custom icons is also possible and will be covered later in this chapter.

Creating and using a custom theme

We've already discussed how powerful theming is in jQuery Mobile. It makes it trivial to develop a rich mobile website with simple and elegant style. Even more powerful is the ability to create your own library of swatches which can be used to make your application or website truly unique. Developing your own theme can be approached in one of the following two ways:

1. Download and open the existing jQuery Mobile CSS file and edit to your heart's content.
2. Point your web browser to ThemeRoller for jQuery Mobile: <http://jquerymobile.com/themeroller/>.

We'll be focusing solely on option two because let's be honest, why wade through all of that CSS when you can point, click, and drag your way to a new theme, full of swatches in 10 minutes? Let's find out what ThemeRoller is all about.

What's ThemeRoller?

ThemeRoller for jQuery Mobile is an extension of a web-based app that was written for the jQuery UI project. It allows users to quickly assemble a theme full of swatches in minutes using drag-and-drop color management. It features an interactive preview so that you can immediately see how your changes affect your theme. It also has a built-in inspector tool which helps you dig into the minute details (should you want them). It also integrates with Adobe® Kuler®, a color management tool. You can download your theme after you're done, you can share it with others via a custom URL, and you can re-import past themes for last-minute tweaking. It's a powerful tool and is a perfect complement to jQuery Mobile.

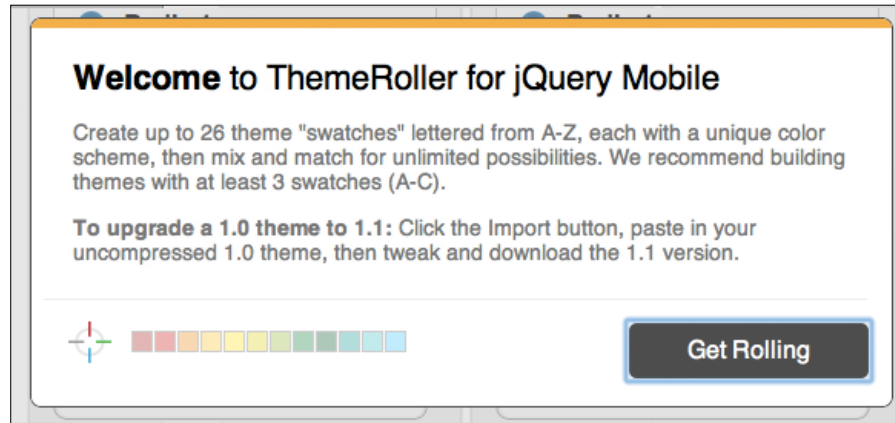

One of the hallmarks of the five default swatches is that the jQuery Mobile team spent quite a bit of time working on readability and usability. The swatches range from highest contrast (A), to lowest contrast (E). Within a single theme the areas which have most contrast are the areas most prominent on the page. This includes the header (and listview headers), and buttons. When creating your own theme it's a good idea to keep this in mind. We always want to focus on usability within our app right? What good is a slick app if no one can read it because of poor color choices?

Using ThemeRoller

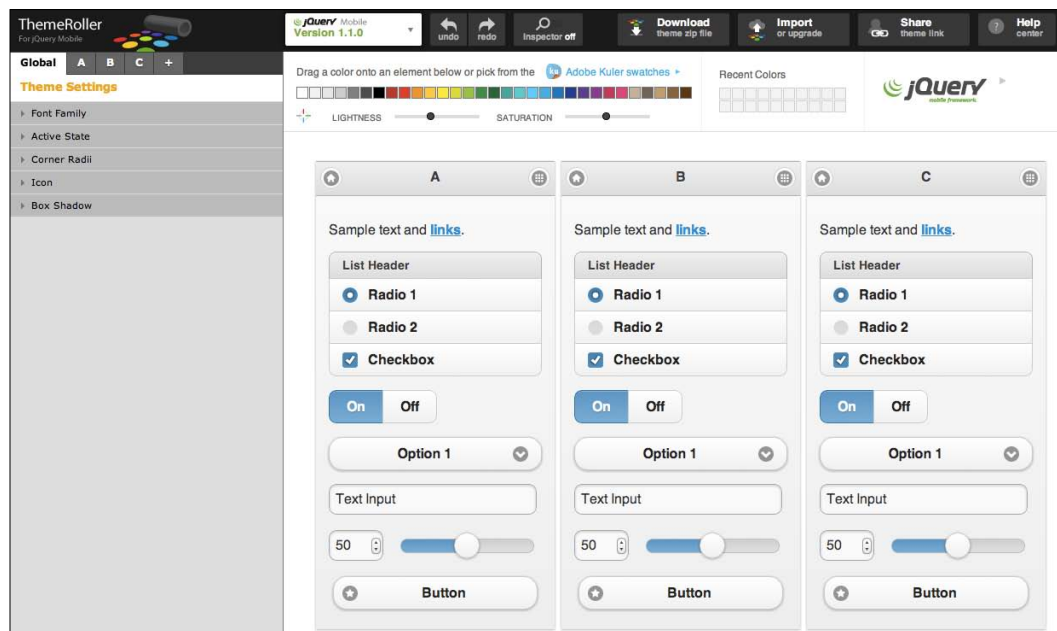

The first thing you'll see when you load up ThemeRoller is a slick looking splash screen, followed by a helpful **Getting Started** screen:

The **Getting Started** screen has some helpful tips so make sure to glance at it before clicking the **Get Rolling** button:

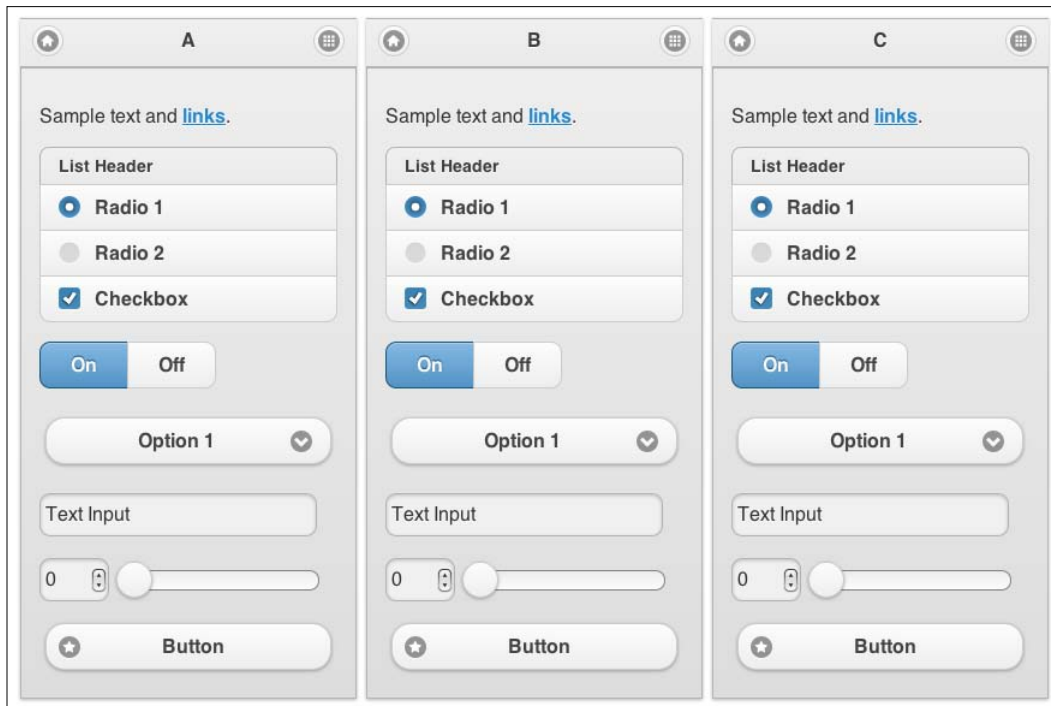

After all of the splash screens are out of the way you'll be presented with the primary interface:

ThemeRoller is broken into four main areas: Preview, Color, Inspector and Tools. Each of these contains important functionality that we need to review. We'll start with the Preview section.

Preview

Unless you're loading an existing theme, the preview area will present three complete, identical and interactive jQuery Mobile pages packed with widgets of all sorts:

Move your mouse over them and you'll see that each page is functional. The header on each page contains a letter indicating which swatch controls its appearance.

Colors

At the top of the page you'll see a series of color chips, along with two slider controls and a toggle button. Further to the right, you'll see another ten color chips which should be blank. These are dedicated to recently used colors and will be empty until you've selected a color:

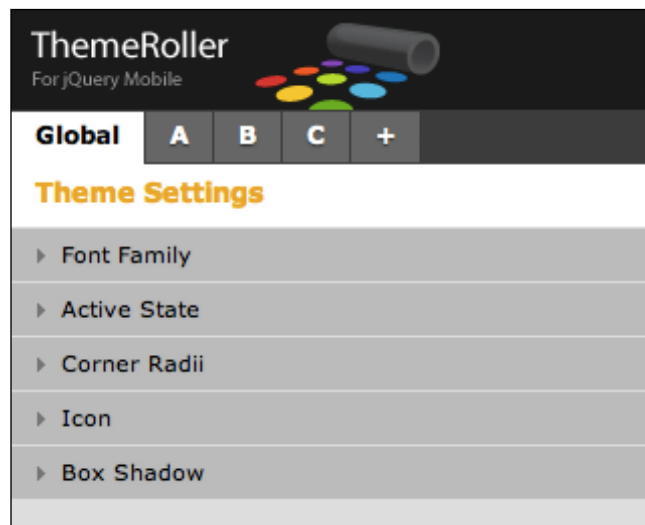

Below the color chips are two sliders labelled **Lightness** and **Saturation**. The lightness slider adjusts the light and dark tones of the series of color swatches, while the saturation makes the colors more, or less, vibrant. Taken together, a user should be able to approximate nearly any color they choose. To use colors from Kuler®, click the text link marked **Adobe Kuler swatches**.

Each of the color chips can be dragged onto any element within the preview area. This makes development of a swatch set extremely easy. Note that many of the jQuery Mobile styles overlap, for example, the header bar at the top of the page receives the same style as the header of the listview. Adjust the colors as desired then drag each chip onto an element on the page. Remember that each individual page is its own swatch so be careful about how you choose to mix colors.

Inspector

On the far left of the interface is the inspector panel, split into two parts. The top part contains buttons allowing developers to download their theme, import an existing theme, and share a link to their theme. There's also a **Help** link for people who didn't buy this book:

The bottom section contains a series of tabs labelled **Global**, **A**, **B**, **C**, and **+**. Each of these tabs holds an accordion panel which contains all of the values for an individual swatch, except for the Global tab which applies to all of the swatches.

Select the **Global** tab, then click **Active State**, and the accordion panel will expand to show settings for the active state for your entire theme. Options include text color, text-shadow, background, and border. Changing a value in the global causes every current (and future) swatch to reflect the new setting.

Additional swatches can be added to your theme in two ways. Clicking the **+** tab at the top of the inspector adds a new swatch at the last place in your theme. You can also add a new swatch by clicking the **Add Swatch** button located at the bottom of the preview area. Swatches can be deleted by selecting the tab with the swatch you want to remove, then clicking the **Delete** link located to the right of the swatch name. Note that deleting a swatch from the top of the stack will cause the remaining swatches to be renamed.

Tools

At the very top of the page there are a series of buttons. These buttons allow you to perform a variety of tasks which we'll cover in a moment, but first, take a closer look at the buttons themselves:

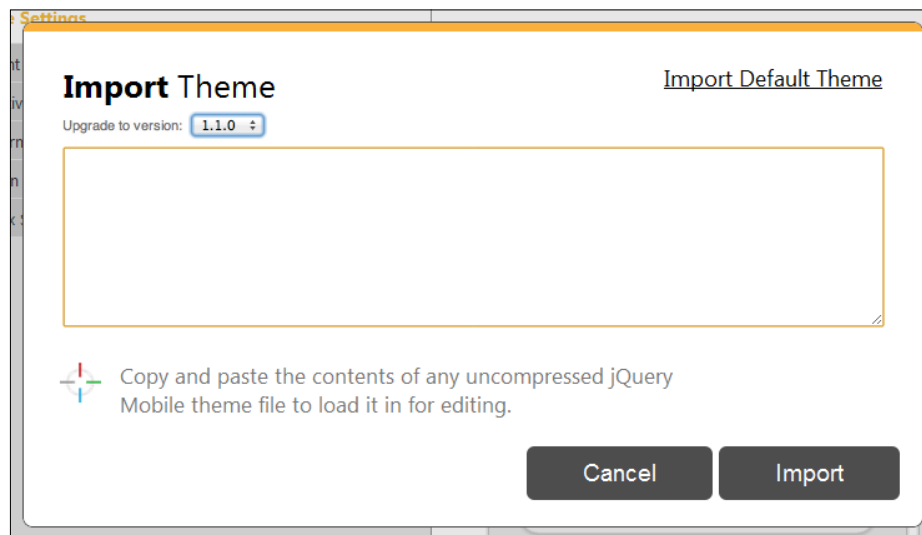

You'll notice the following buttons: a switch allowing you to change between the 1.1 (current) Version and the 1.0.1 Version, undo/redo, and a toggle button for the inspector. Setting this toggle to on allows you to inspect any widget in the preview area. Hovering over a widget highlights that element with a blue box. Clicking the element will cause the accordion menu in the Inspector area to expand to display settings specific to that element.

There are four additional buttons which allow you to download your theme, import or upgrade a previously created theme, share your theme with others, and a help button.

Creating a theme for Notekeeper

Now that we're familiar with the ThemeRoller interface, how about we go ahead and create our first theme? Rather than build one in abstract, let's create one that we'll actually use for the Notekeeper app we built earlier. Let's start simply by modifying one of the existing themes that is shipped with jQuery Mobile. The team was kind enough to let users import the default themes as a starting place for new themes, so that's where we'll head first. Click the **Import** button at the top left of the window and you'll get a box allowing you to paste in the contents of an existing theme:

Import the default theme by clicking the link in the top-right corner, appropriately titled **Import Default Theme**. After the textarea fills with CSS, click **Import**. The preview area will reload and display swatches from **A** to **E**.

We'll focus our efforts on changing up the white swatch, **D**, as it's the closest to what our end goal is. Since we'd rather use swatch **A** as the name, let's delete the other swatches so that only **D** is left. Remember that ThemeRoller renames swatches as others are deleted. That means when you delete swatch **A**, **B** becomes **A**, **C** becomes **D**, and so on.

Keep going until the swatch that was **D** is now in the **A** position. Finally, delete swatch **B** (which was formerly swatch **E**) so that all we have left is swatch **A**:

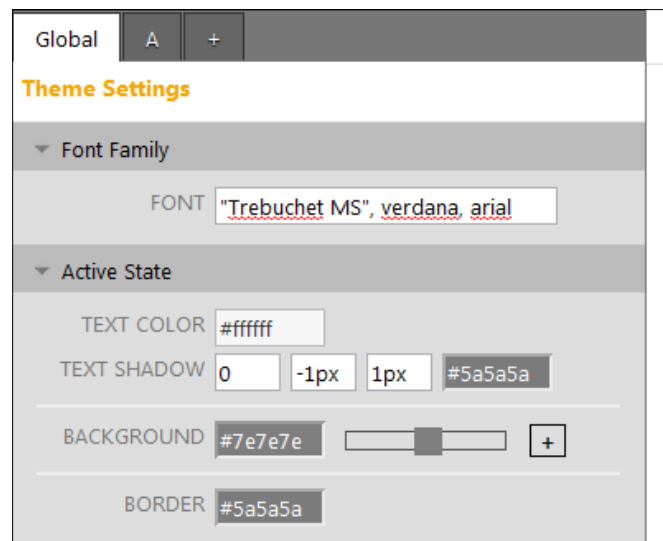

This swatch is nice looking but it's a little bland. Let's inject a little color by changing the header to a nice green. The simplest way to determine what values should be changed for any element is to use the inspector. Toggle the inspector to **On** at the top, then click anywhere on the header of theme **A**. You'll know if you got it right if the **A** tab is selected on the left, and the **Header/Footer Bar** panel expands:

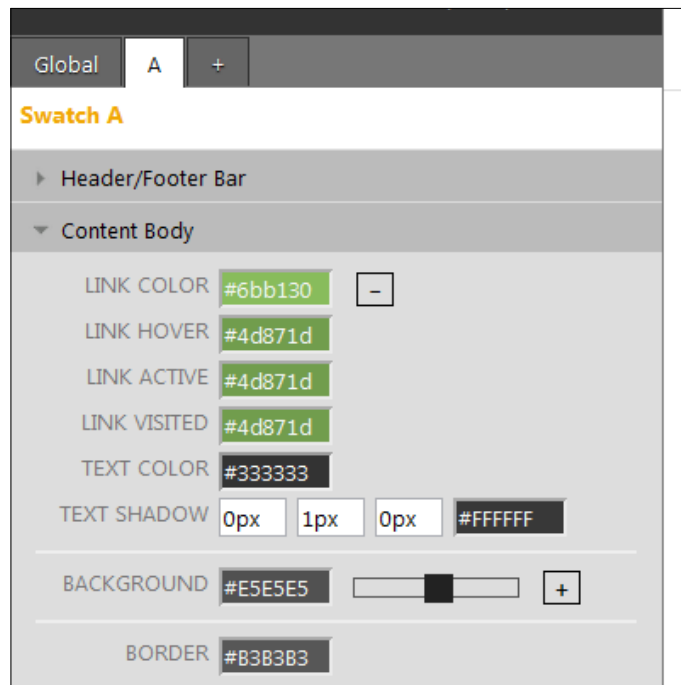

You can change the color in one of a few ways. You can drag a color chip from the top directly onto the background. You can also drag a color chip onto an input field. Finally you can manually input the value. Notice that when you click into a field containing a color value you're provided with a slick color picker. Go ahead and change the values in the input fields in this panel to the values shown in the previous screenshot.

Looking good, but now the blue from the theme's active state clashes with our green. Using the inspector tool, click once on the **On** section of the On/Off toggle bar. This should cause the **Active State** panel within the **Global** tab to expand. We'll change the blue to a nice warm grey. The Global panel should now look similar to the following screenshot:

There's only one thing that's keeping our new theme from looking its hottest, the blue text link in the paragraph at the top. Going back to our trusty inspector, let's click directly on the link which will expand the **Content Body** panel within the **A** tab. Now, for those already familiar with CSS you know that you can't simply change the link color without changing the hover also, `visited: hover`, and active states. The problem is that there are no options to make those changes, but ThemeRoller has you covered. Click the **+** to the right of the **Link Color** input field to display the rest of the options, then change the colors, as shown in the following screenshot:

And that's that. Feel free to make additional changes to your theme as you explore the inspector area. Change whatever you like, it's just bits and bytes right now. Keep in mind though that there's no undo option at the time. If you really like something, consider writing down the values so that you don't lose them or exporting it as it is. Speaking of...

Exporting your theme

Before we actually export our theme there's one thing that must be noted. Remember the splash page with the "helpful" information? It turns out that there's one piece that's not a recommendation, but a requirement.

We recommend building themes with at least 3 swatches (A-C).

For our theme to apply to our Notekeeper app properly we'll need to duplicate our single swatch (letter **A**) to swatches **B** and **C**. Luckily this is an easy thing to do. Select the **A** tab at the top of the inspector, then click the **+** tab twice. What you should see is three identical swatches, and now we're done.

Now that we've finished our theme we're going to export it for use in our Notekeeper application. This is a straightforward process which begins by clicking the **Download Theme** button located in the middle of the page, at the top of the interface. You'll be presented with a box allowing you to name your theme, some information about how to apply your theme, and a button labelled **Download Zip**. After naming our theme Notekeeper, click the **Download Zip** button and you'll receive a tasty little morsel in your downloads folder.

Extract the contents of the ZIP file and you'll see the following directory structure:

- index.html
- themes/
 - Notekeeper.css (The uncompressed version of your theme)
 - Notekeeper.min.css (The compressed version. Use this in production)
 - images/
 - ajax-loader.gif
 - icons-18-black.png
 - icons-18-white.png
 - icons-36-black.png
 - icons-36-white.png

The HTML file at the top of the tree contains information on how to implement your theme, as well as a few widgets to confirm that the theme works. All of the links are relative in the example file, so you should be able to drag it into any browser window and see the results.

A few notes about the download and implementation of themes:

1. The jQuery team provides the icons for buttons to you in this ZIP file for a reason. The theme requires those images to be relative to the CSS file. This means that unless you're already using the default themes you need to also include the images folder when you upload your theme to your website or the icons won't show up.

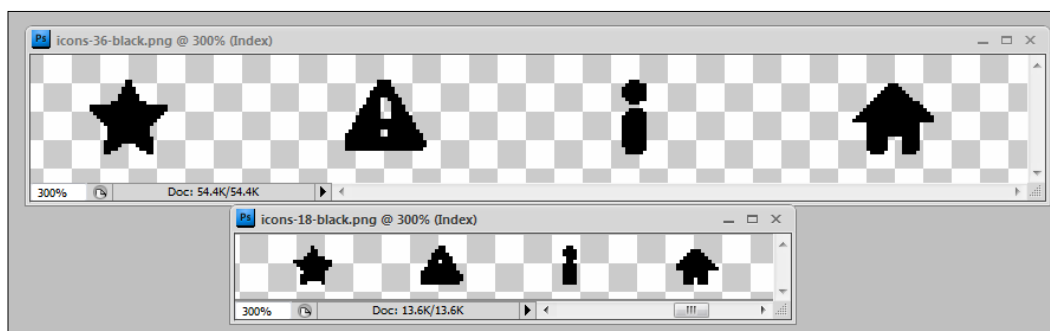

2. **Hang on to the uncompressed version of your theme.** While you don't want to use it in production because of the size, you will need it should you ever wish to edit it within ThemeRoller. ThemeRoller cannot, at the time of this writing, import the minified CSS file.

Creating and using custom icons

We've seen how easy it is to add our own theme to jQuery Mobile using ThemeRoller. Now we're going to add a little more spice to our Notekeeper application by creating a custom icon. The directions in this section will be specific to Photoshop but any graphics application capable of exporting transparent PNG files should be acceptable.

CSS Sprites

Before we create and use an icon, we should first understand how jQuery Mobile uses icons and applies them. In the theme you just created there are several image files present (themes/images). Open `icons-18-black.png`, and `icons-36-black.png` in the graphics editor of your choice. Zoom in on both of them to 400% or so and you should see something very similar to the following image:

When opening each of these files you'll probably notice that each image contains all the icons. This is because jQuery Mobile takes advantage of a technique called **CSS Sprites** which itself takes advantage of the fact that CSS allows developers to *crop* a background image by specifying its position within its container, and to hide any other part of the background that would normally display outside of that container. Its primary benefits include the following:

1. Reducing the number of requests a browser has to make. Fewer requests generally mean that a page will load faster.
2. Centralize image locations. All icons can be found in one location.

The following screenshot is a simple illustration of the technique:

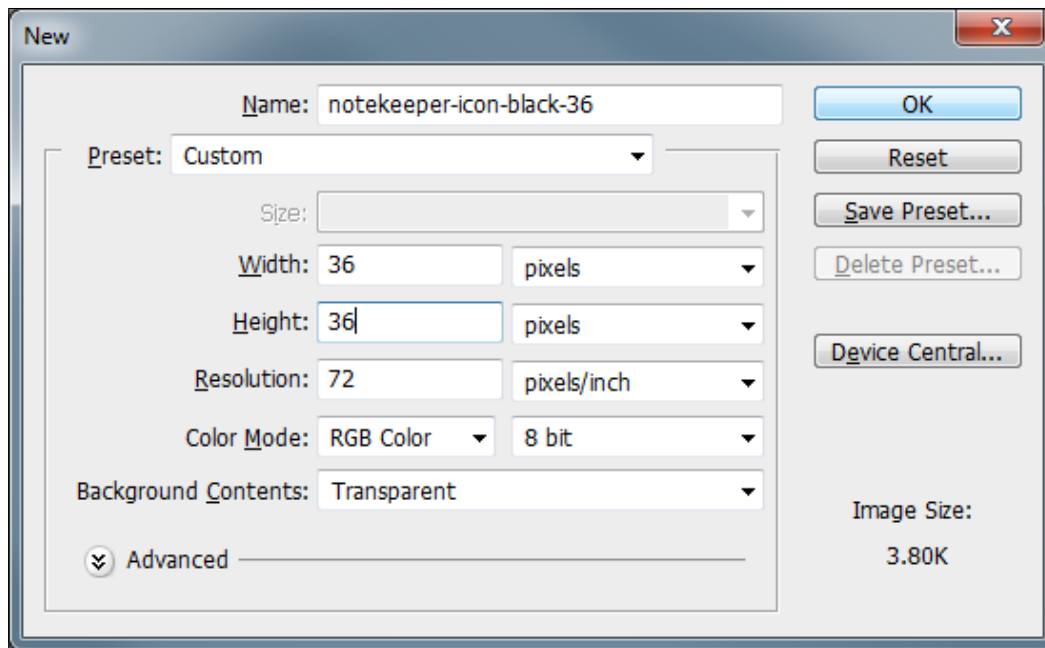

A browser always refers to an image from its top-left corner. In CSS language that's 0, 0. To achieve this effect you set the background image on a container then simply adjust the x and y coordinates until the position of the image matches your design. Then set the overflow of the container to crop, or hide, the remainder of the image. Remember that you're *moving* the image to the left so you'll use negative numbers for the x position. Using the previous illustration as a reference, the following code snippet is used to achieve this effect:

```
<html>
  <head>
    <title></title>
    <style>
      div {
        background: url("icons-36-black.png");
        background-position: -929px 4px;
        background-repeat: no-repeat;
        border: 1px solid #000000;
        height: 44px;
        overflow: hidden;
        width: 44px;
      }
    </style>
  </head>
  <body>
    <div></div>
  </body>
</html>
```

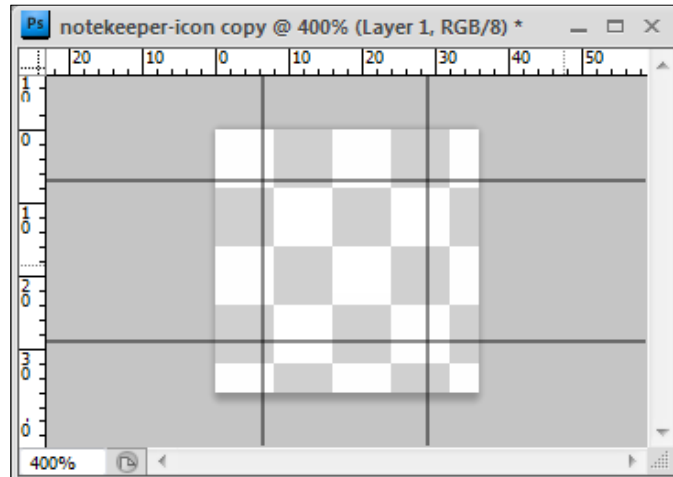

Designing your first icon

We're only going to be creating a single icon so we won't quite need all of the empty space around the icon. Let's start by deciding what we want to illustrate. Our application is called Notekeeper and it creates notes. Perhaps an icon illustrating a sheet of paper would work? This would have the added benefit of being fairly easy to represent at a small size. In the image editor of your choice create a new document at 36x36 pixels at 72 dpi. Name it `notekeeper-icon-black-36.png`:

Even though the dimensions of the document are 36x36 pixels, the active area of the icon will only be 22x22 pixels. This is in keeping with the icons provided by the jQuery Mobile team and will make sure our icon doesn't look odd. To make it easier to stay within the lines, use the rectangular selection tool to draw a square at 22px, then position it 7px from the top edge of the document and 7px from the left.

Next draw guides along each edge so that your document looks something similar to the following screenshot:

When drawing icons, you want to keep in mind the dimensions and attributes of the thing being illustrated. You won't be able to represent everything, but you need to communicate the spirit of the thing. A sheet of paper is taller than it is wide, and has lines on it. Let's start with those two things and see what we can come up with. The other icons in the set have a thick feel to them so that they can stand out against the background. Let's color in a solid shape, then delete the lines for the page so that the icon has the same thick feel. We're going to draw the lines in black so that they show up better printed in the book, but our icons will need to be white. Make sure you adjust your design accordingly:

This icon seems to meet all of our criteria. It's taller than it is wide, and has lines just like paper. It also has a jaunty little page turn to give it some attitude. Isn't that what everyone looks for in their paper icon? Make sure that the icon's lines are white, then save it. The jQuery Mobile icons have been saved as transparent PNG-8 files. This is similar to the GIF format, but isn't required. Use transparent GIF or transparent PNG-24 if you wish.

When we created our first icon, we created the high resolution version. For brevity's sake we're going to quickly walk through the steps of creating a low-resolution icon:

1. Create a new image document at 18x18 pixels. Name this one `notekeeper-icon-18`.
2. The active area of this icon will be 12x12 pixels. Draw a selection 12px square then position it 3px from the top, and 3px from the left.
3. Draw your guides then sketch out the icon using the previous version as a reference. It's a lot harder drawing with this little space isn't it?
4. Your final result should look similar to the following screenshot:

Save both images along with your Notekeeper theme and close Photoshop.

High and low resolution

Resolution is the number of dots, or pixels, that can be displayed into a given area. Those of you from the web world measure everything in 72dpi, because that's what most monitors display. If you have much experience with mobiles then you might know that each device can have a different resolution compared to the one next to it. The problem with this is that higher resolution devices simply display more pixels on screen. This means that an image displayed on a high resolution screen will be smaller than the same image on a low resolution screen.

jQuery Mobile accounts for this by having two versions of each icon, along with two sets of code for high and low resolution devices. In the next section we'll apply our custom theme and custom icon to our Notekeeper application.

Updating the Notekeeper app

It's time for us to tie all of these loose ends together. We have a custom theme that we built using ThemeRoller, we've got our sweet custom icon, and now it's time for us to put all the pieces together. You'll need the following pieces to finish up:

1. The code you completed at the end of the Notekeeper chapter.
2. The custom theme you created earlier in this chapter.
3. Your custom icon; in white; in both 18px and 36px sizes.

Adding our custom theme

Let's start with the easiest part. Adding in our custom theme is pretty simple. Open `notekeeper.html` (in your browser, and in the text editor of your choice). Look for the `<head>` tag and add the following lines:

```
<title>Notekeeper</title>
<meta name="viewport" content="width=device-width, initial-scale=1">
<link rel="stylesheet" href="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.css" />
<link rel="stylesheet" href="themes/Notekeeper.min.css" />
<link rel="stylesheet" href="styles.css" />
<script src="http://code.jquery.com/jquery-1.6.4.js"></script>
<script src="http://code.jquery.com/mobile/
  latest/jquery.mobile.min.js"></script>
<script src="application.js"></script>
```

The first new line implements the new theme we created. The second line currently points to a missing file (because we haven't created it yet). Even with a rich theming system such as jQuery Mobile has, we're still going to have some custom CSS for various things. `styles.css` is where we'll put our assorted styles, especially the definitions for our custom icon.

By the way, go ahead and reload your browser window and take a look at our new theme in action. Isn't it snazzy? It's going to look even snazzier in a few minutes when our custom icon appears.

Adding our custom icon

Go ahead and create `styles.css` in the root of your Notekeeper application code, then open it. The first thing we'll do is to add in the declaration for our 18px icon. It's low-resolution and will be the one you'll see in your desktop browser. High-resolution icons only show up in iPhone 4 and iPhone 4S at the moment.

To add our custom icon we follow the pattern set by jQuery Mobile. It applies icons to buttons and other elements using the `.ui-icon` prefix. This means that for our icon to work within the framework we have to name our CSS class as follows:

```
.ui-icon-notekeeper-note {
    background-image: url("themes/images/notekeeper-icon-white-18.png");
}
```

Then adding the icon to our Add Note button is as simple as adding a `data-icon` attribute, as shown in the following lines of code:

```
<div class="ui-block-b">
    <input id="btnAddNote" type="button" value="Add Note" data-
        icon="notekeeper-note" />
</div>
```

Keep in mind that the string `notekeeper-note` can be anything as long as it matches the second half of the CSS class you created earlier. Finally let's add the remaining piece to our app, the high-resolution icon.

One of the hallmarks of jQuery Mobile is its support for something called **media queries**. Media queries essentially allows you to query a given device for various pieces of information based on its media type: screen, print, tv, handheld, and several others. The answer to this query allows developers to branch CSS code and display the page one way for a desktop browser (screen), and another way for a TV (tv). In the case of our icons, we want to ask any viewing device with a type of screen, if it supports a property called `-webkit-min-device-pixel-ratio` and if the value of that property is 2. Add the following lines to `styles.css` after the declaration for the low-resolution icon:

```
@media only screen and (-webkit-min-device-pixel-ratio: 2) {
    .ui-icon-notekeeper-note {
        background-image: url("themes/images/notekeeper-icon-white-36.
png");
        background-size: 18px 18px;
    }
}
```

Other than the media query code the only thing unique about this is the `background-size` property. It allows developers to specify that a given background should be scaled to the specified size (18x18 pixels) rather than its original size of 36x36 pixels. Since the resolution on the iPhone 4 and 4S is exactly double the size of the low-resolution devices this means that we're packing double the pixels into the same space as the smaller icon. The end result is that the icon looks crisper and sharper. If you've got one of these devices, upload your code to a server and view it. Your patience will be rewarded.

Summary

In this chapter, we learned about advanced CSS techniques that are central to the jQuery Mobile experience, and how jQuery Mobile uses them to provide a rich interface to the end user. We took a deep dive into the basics of jQuery Mobile theming and how it works. We built a custom theme using the ThemeRoller tool, a custom icon with our very own hands, and we learned how to tie all those things together and implement them in our application.

In the next chapter, you'll learn how to take the principles you've learned in the past 11 chapters and create a native application which can run on the iOS and Android platforms (along with several others), using the Phonegap open source library.

12

Creating Native Applications

In this chapter, we will look at how to turn jQuery Mobile based web applications into native applications for mobile devices. We'll discuss the PhoneGap framework and how it allows you to tap into your device's hardware.

In this chapter, we will:

- Discuss the PhoneGap project and what it does
- Demonstrate how to use PhoneGap's Build service to create native applications

HTML as a native application

For most folks, creating a native application on a platform like Android or iOS requires learning an entirely new programming language. While it is always good to learn new languages and expand your skill set, wouldn't it be cool if you could take your existing HTML skills and use them natively on a mobile device?

Luckily there is just such a platform. PhoneGap (<http://www.phonegap.com>) is an open source project that allows you to take HTML pages and create native applications. This code is entirely free and can be used to develop applications for iOS (both iPhone and iPad), Android (again both phones and tablets), Blackberry, WebOS, Windows Phone 7, Symbian, and Bada. PhoneGap works by creating a project in the native environment and pointing to an HTML file. Once setup, you can use your existing HTML, CSS, and JavaScript skills to create the UI and functionality of your application.

Even better, PhoneGap provides additional APIs to your JavaScript code. These APIs allow for:

- Accelerometer: Allows your code to detect basic movement on the device
- Camera: Allows your code to work with the camera
- Compass: Gives you access to the compass on the device
- Contacts: Provides basic search and contact creation support
- File: Read/write access to the device's storage
- Geolocation: Provides a way to detect the location of the device
- Media: Allows for basic video/audio capture support
- Network: Determines the network connectivity settings of the device
- Notification: A simple way to create a notification (via a pop up, sound, or vibration)
- Storage: Access to a simple SQL database

By using these APIs, you can take normal HTML sites and turn them into powerful, native-like applications that users can download and install on their devices.

Before we go any further, let's take a quick note on **PhoneGap**. PhoneGap is an open source project currently in incubation status at Apache. It has been renamed as **Cordova**. You may hear people refer to it by either name. At the time this book was written, most people still referred to the project as PhoneGap and that is the term we will use. The important thing to remember is that PhoneGap is free and open source!

Before we go further, let's talk quickly about how a PhoneGap application compares to a native application. Native applications – in most cases – will perform faster than applications created with PhoneGap. PhoneGap is not meant to replace native development. But by allowing you to use existing skills and deploy to multiple platforms at once, the benefits can far outweigh any concerns over performance.

Working with PhoneGap

Creating a PhoneGap project is done via two main methods. The primary way people use PhoneGap is by using the development tool of the platform they are building for first. So, for an Android project, that involves using the Eclipse editor with the right plugins, and on iOS it involves XCode. The *Get Started Guide* (<http://www.phonegap.com/start>) provides details on how to set up your environment for the device platform of your choice:

Get Started Guide

Pick your platform

 iOS

 Android

 BlackBerry

Video Tutorials

1. Requirements

- Intel-based computer with Mac OS X Snow Leopard (10.6)

Necessary for installing on Device:

- An Apple iOS device (iPhone, iPad, iPod Touch)
- iOS developer certification

2. Install SDK + PhoneGap

 Download and install Xcode from [Apple Developer Portal](#) (Membership required)

 [Download](#) the latest copy of PhoneGap and extract its contents. Navigate to the iOS directory and run the installer until completion.

3. Setup New Project

- Launch Xcode, then under the File menu select **New** and then **New Project...**
- Select **PhoneGap-based Application** from the list of templates

Choose a template for your new project:

Detailing the setup for each platform would be too much for this book (and would just duplicate what's on the PhoneGap website), so instead we will focus on the other option for creating native applications, the **PhoneGap Build** service. PhoneGap Build (<https://build.phonegap.com>) is an online service that simplifies and automates the process of creating native applications. It allows you to simply upload code (or use a public source control repository) to generate the native binaries. Even better, you can use PhoneGap Build to generate binaries for all their supported platforms. That means you can write your code and spit out code for an iPhone, Android, Blackberry, and other versions, all from the site itself:

PhoneGap:Build

Write once. Compile in the cloud. Run anywhere.

[Sign in](#)

[Create an account](#)

Take the pain out of compiling mobile apps for multiple platforms

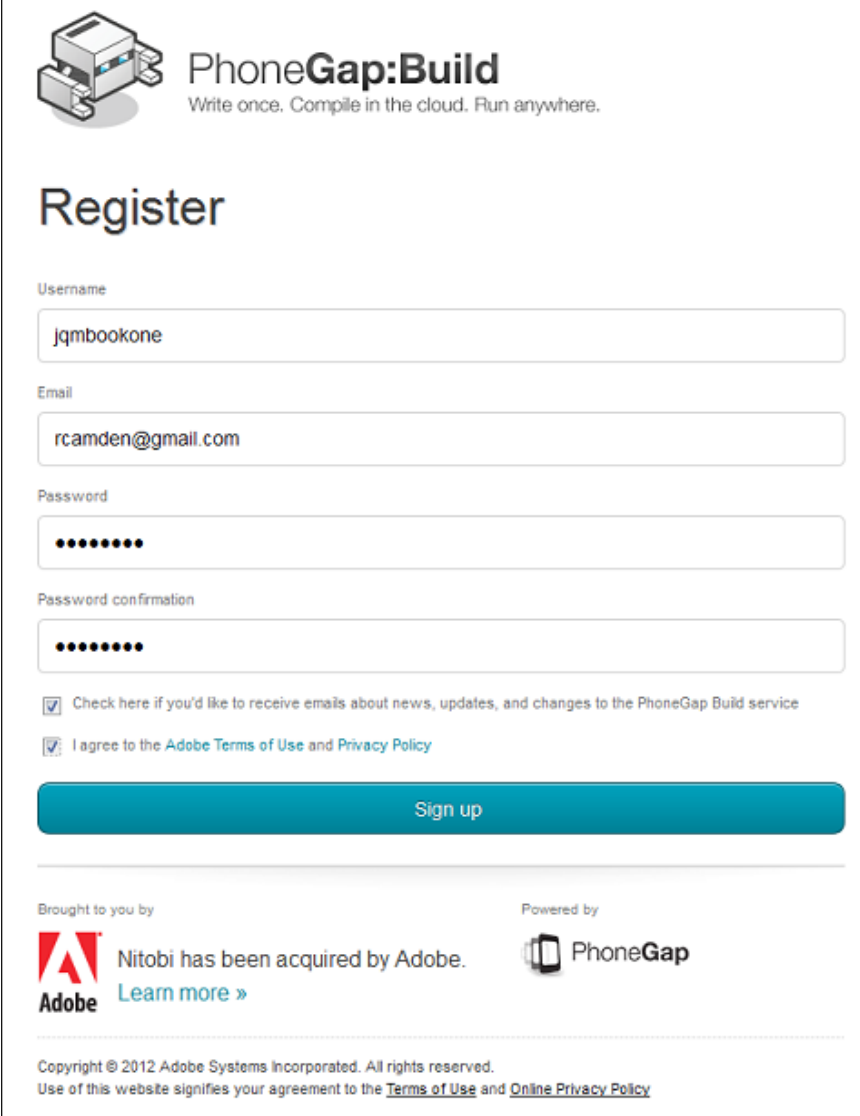

Say goodbye to SDKs, compilers and hardware. Simply write your app using HTML, CSS or JavaScript, upload it to the PhoneGap Build service and get back app-store ready apps for Apple iOS, Google Android, Palm, Symbian, BlackBerry and more.

By compiling in the cloud with PhoneGap Build, you get all the benefits of cross-platform development but can still build apps just the way you like.

Want to know more? [Check out our FAQs.](#)

The PhoneGap Build service is not free, though. Pricing plans and other details may be found on the site, but luckily there is a free Developer plan. That is the service we'll be using for this chapter. Let's begin by creating an account. (In the screen shots and examples that follow, be sure to change the details to something specific for you.)

Begin by clicking the **Creating an account** button and filling out the pertinent details:

The image shows a web form for registering an account on PhoneGap Build. At the top left is the PhoneGap Build logo, which consists of a stylized mobile phone icon and the text "PhoneGap:Build". Below the logo is the tagline "Write once. Compile in the cloud. Run anywhere." The main heading of the form is "Register". Below this heading are four input fields: "Username" with the value "jqmbookone", "Email" with the value "rcamden@gmail.com", "Password" with masked characters, and "Password confirmation" with masked characters. Below the password fields are two checkboxes: the first is checked and labeled "Check here if you'd like to receive emails about news, updates, and changes to the PhoneGap Build service"; the second is checked and labeled "I agree to the [Adobe Terms of Use](#) and [Privacy Policy](#)". Below these checkboxes is a large blue button labeled "Sign up". At the bottom of the form, there are two sections: "Brought to you by" featuring the Adobe logo and the text "Nitobi has been acquired by Adobe. [Learn more »](#)", and "Powered by" featuring the PhoneGap logo. At the very bottom, there is a copyright notice: "Copyright © 2012 Adobe Systems Incorporated. All rights reserved. Use of this website signifies your agreement to the [Terms of Use](#) and [Online Privacy Policy](#)".

After you sign up, you will be returned to the PhoneGap Build home page and you will not see any type of confirmation message. This is a bit unfortunate, but if you check your e-mail, you should see a message from them asking to verify your sign-up. Click that link, and you'll be taken to a page asking you to create your first PhoneGap Build project:

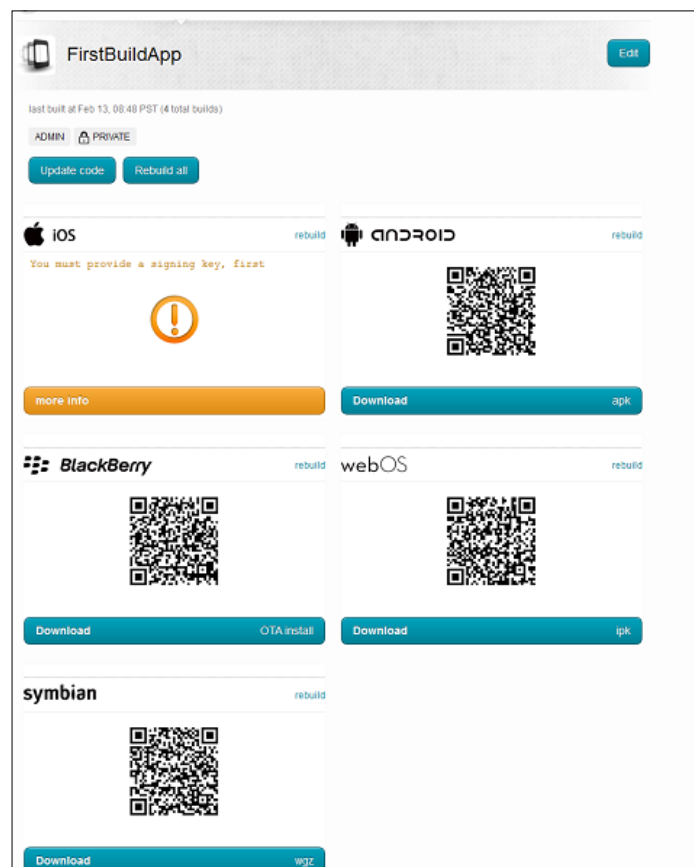

The image shows a web browser window displaying the PhoneGap Build interface. At the top, there is a navigation bar with the PhoneGap Build logo, links for 'Apps', 'Docs', 'Blog', and 'Help', and a user profile section showing 'rtamden@gmail.com' and a 'sign out' link. Below the navigation bar, a large heading reads 'Welcome to PhoneGap Build!'. The main content area features a modal dialog box titled 'Create a new application'. Inside this dialog, there is a yellow instructional box that says: 'Get started by adding your application. If you want to kick the tires quickly, just copy & paste the sample repo below into the url field: http://github.com/phonegap/phonegap-start.git'. Below this, there is a text input field labeled 'Your app name'. Underneath the input field are two checkboxes: 'enable debugging' (unchecked) and 'make app private' (checked). Below the checkboxes is a section titled 'select upload method' with three radio button options: 'create a new git repository' (selected), 'pull from a git/svn repo url', and 'upload an archive or index.html file'. At the bottom right of the dialog are two buttons: 'Cancel' and 'Create'.

Notice that the Build service supports seeding a project from a new Github repository, an existing Git or Subversion repository, or via an uploaded ZIP or HTML file. At this point, let's switch away from the website and back to code. We want to begin with a very simple set of code. Later on in the chapter we will do something a bit more interesting, but for now, our objective is to just upload some HTML and see what comes next. In the code you downloaded from GitHub, open the `c12` folder and look at the `app1` folder. This contains a copy of one of the list examples from *Chapter 4, Working with Lists*. It uses jQuery Mobile to create a simple list of four people, along with thumbnail pictures. Nothing too exciting, but it gets the job done for our purposes here. You will notice that there is already an `app1.zip` file.

If you go back to the website and select **upload an archive**, you can then browse to the location on your computer where you extracted the files and select that ZIP file. Be sure to also enter a name for the application. I chose `FirstBuildApp`. After hitting **Create**, you are then taken to a page with all your apps, which if you are a new Build user will only contain the one just created:

Clicking on the app title then gives you the option to download various flavors of the application. Believe it or not – you are already able to download a version for most platforms. Working with iOS requires you to provide additional details though:

If you do not see a **Download** link but rather a **Queued** notice, please give the Build service a minute or two to catch up. If you simply reload the page, you will see the link show up eventually.

Actually using the applications depends on your platform of choice. For Android, you need to ensure that you have enabled the setting, **Allow installation of non-Market applications**. The exact wording and location of that setting will depend on your device. That phrase was found in the **Applications** setting on my HTC Inspire device. You can sign the application by editing the settings on the PhoneGap Build site. Once you've done that, you can actually submit your application to the Android Market. But since Android allows you to play with applications that are not signed, you can skip that step while testing. If you download the APK (the actual file representing your application), you can get it on your device in a few ways. The Android SDK includes tools to install applications from the command line. The easiest way would be to use your e-mail. If you e-mail the file to yourself and check your e-mail on your device, you should be able to install it there. The following screenshot shows the application running on my phone:

Adding PhoneGap functionality

We just demonstrated how to use the PhoneGap Build service to turn HTML (and JavaScript, CSS, and images of course) into a real, native application for multiple platforms. As mentioned earlier in the chapter though, PhoneGap provides more than a simple wrapper to turn HTML into native applications. The PhoneGap JavaScript API provides access to a number of cool device-centric services that can greatly enhance the power of your application. For our second example, we'll take a look at one of these features – the Contacts API. (For full details, see the *Contacts API documentation* which is available at: http://docs.phonegap.com/en/1.4.1/phonegap_contacts_contacts.md.html#Contacts).

The application in Listing 12-1 is a simple contact search tool. Let's take a look at the code and then cover what's going on:

Listing 12-1: index.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Contact Search</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="jquery.mobile.min.css" />
    <script src="jquery.js"></script>
    <script src="jquery.mobile.min.js"></script>
    <script src="phonegap-1.4.1.js"></script>
    <script>
      document.addEventListener("deviceready", onDeviceReady, false);
      function onDeviceReady() {
        $("#searchButton").bind("touchend", function() {
          var search = $.trim($("#search").val());
          if(search == "") return;
          var opt = new ContactFindOptions();
          opt.filter = search;
          opt.multiple = true;
          navigator.contacts.find(["displayName", "emails"],
            foundContacts, errorContacts, opt);
        });
        foundContacts = function(matches) {
          //create results in our list
          var s = "";
          for (var i = 0; i < matches.length; i++) {
            s += "<li>" + matches[i].displayName + "</li>";
          }
          $("#results").html(s);
        }
      }
    </script>
  </head>
  <body>
    <div>
      <input type="text" value="Search" />
      <input type="button" value="Search" />
    </div>
    <div id="results">
    </div>
  </body>
</html>
```

```
        $("#results").listview("refresh");
    }
    errorContacts = function(err) {
        navigator.notification.alert("Sorry, we had a problem and
gave        up.", function() {});
    }
}
</script>
</head>
<body>
    <div data-role="page">
        <div data-role="header">
            <h1>Contact Search</h1>
        </div>
        <div data-role="content">
            <input type="text" id="search" value="adam" />
            <button id="searchButton">Search</button>
            <ul id="results" data-role="listview" data-inset="true"></
ul>
        </div>
    </div>
</div>
</div>
</body>
</html>
```

Let's begin by looking at the layout portion of the application which resides in the bottom half of the file. You can see our jQuery Mobile page structure, and within it, an input field, a button, and an empty list. The idea here is that the user will enter a name to search for, hit the button, and the results will show up within the list. The following screenshot demonstrates the output:

Now take a look at the JavaScript code. The first change we've made is to include the PhoneGap JavaScript library:

```
<script src="phonegap-1.4.1.js"></script>
```

This JavaScript library is available from the ZIP file you download from PhoneGap. Even though we aren't going to be building our application locally (although you certainly can), we need to include the JavaScript file in the ZIP file we send up to the Build service. Here's the one tricky part. As of PhoneGap v 1.4.1, the JavaScript file is unique per platform. That means there is a different JavaScript file for each of the operating systems supported by PhoneGap. The Build service is smart enough to swap out your file reference with the right file for the right platform. If you use the code from the Github repository for this book, it is the Android version. If you wish to take this code and work with it for iOS, be sure to replace the JavaScript file locally.

The next interesting tidbit is the following line of code:

```
document.addEventListener("deviceready", onDeviceReady, false);
```

The `deviceready` event is a special event fired by PhoneGap. It essentially means that your code can now make use of advanced functionality, such as the Contacts API.

Within the event handler `onDeviceReady`, we have a few things going on. The first function of note is the event handler for the search button. The first few lines simply get, trim, and validate the value.

After we are sure there's actually something to search for, you can see the first actual use of the Contacts API, as shown in the following code snippet:

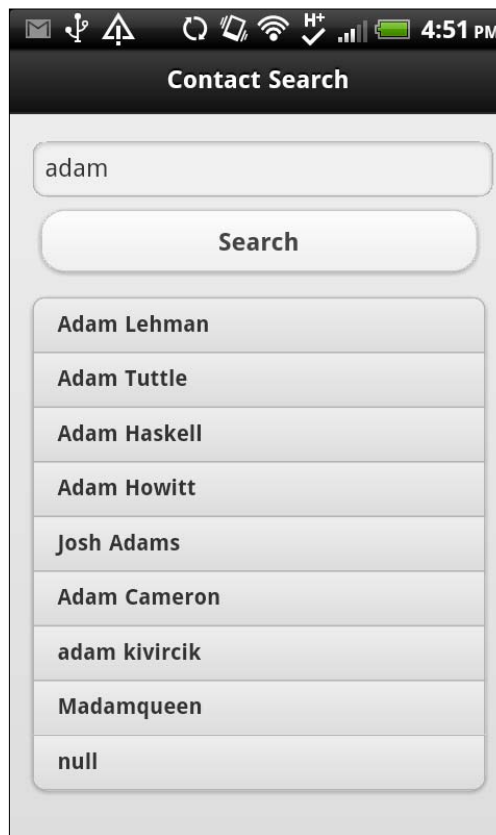

```
var opt = new ContactFindOptions();
opt.filter = search;
opt.multiple = true;
navigator.contacts.find(["displayName","emails"], foundContacts,
    errorContacts, opt);
```

The Contacts API has a search method. Its first argument is an array of fields to both search and return. In our case, we are saying we want to search against the name and e-mail values for contacts. The second and third arguments are the success and error callbacks. The final option is a set of options for the search. You can see it created before the call. The filter key is simply the search term. By default, contact searches return one result, so we specifically ask for multiple results as well.

Now let's take a look at the success handler:

```
foundContacts = function(matches) {  
    //create results in our list  
    var s = "";  
    for (var i = 0; i < matches.length; i++) {  
        s += "<li>" + matches[i].displayName + "</li>";  
    }  
    $("#results").html(s);  
    $("#results").listview("refresh");  
}
```

The result of the contact search will be an array of results. Remember that you only get back what you asked for, so our result objects contain the `displayName` and `emails` property. For now, our code simply takes the `displayName` and adds it to the list. Remembering what we learned from one of the previous chapters, we also know that we need to refresh the jQuery Mobile listview whenever we modify it. The following screenshot shows a sample search:

Summary

In this chapter, we looked into the PhoneGap open source project and how it allows you to take your HTML, JavaScript, and CSS, and create native applications for a multitude of different devices. We played with the Build service and used it to upload our code and download compiled native applications. While jQuery Mobile isn't required with PhoneGap, the two make an incredibly powerful team.

In the next chapter, we'll take this team and create our final application, a full-fledged RSS reader.

13

Becoming an expert - Build an RSS Reader application

Now that you've been introduced to jQuery Mobile and its features, it's time to build our final, full application – an RSS Reader.

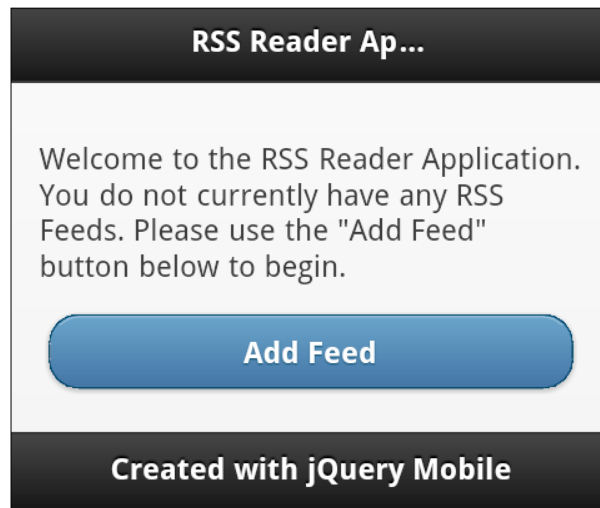

In this chapter, we will:

- Discuss the RSS Reader application and its features
- Create the application
- Discuss what could be added to the application

RSS Reader – the application

Before diving into the code, it may make sense to quickly demonstrate the application in its final working form so you can see the pieces and how they work together. The RSS Reader application is exactly that, an application meant to take RSS feeds (for example from CNN, ESPN, and other sites), parse them into readable data, and provide a way for the user to view the articles. This application will allow you to add and delete feeds, providing both a name and a URL, and then provide a way to view the current entries from the feed.

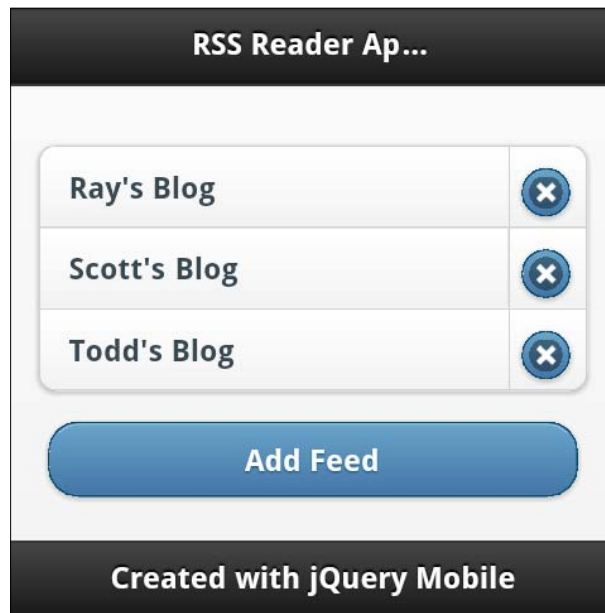

The application begins with a basic set of instructions. These instructions are only visible when you run the application without any known feeds:

Clicking the **Add Feed** button brings you to a simple form allowing for both a name and a URL. (Unfortunately the URL has to be typed in manually. Luckily modern mobile devices allow for copy and paste. I'd strongly recommend using that!):

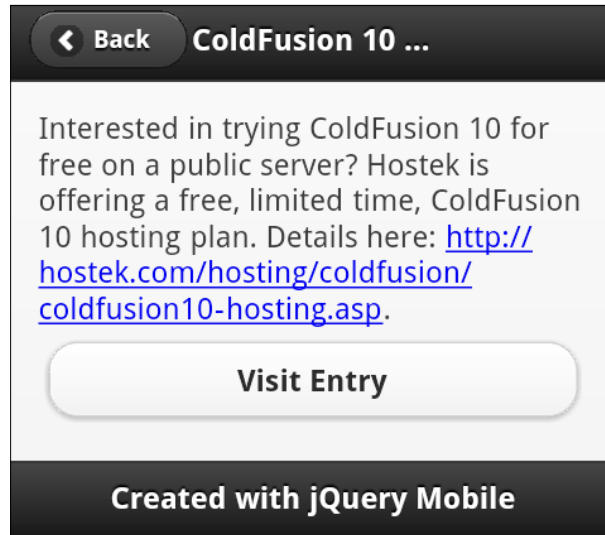

After adding the feed, you are returned back to the home page. The following screenshot shows the view after a few feeds are added:

To begin reading entries, the user simply selects one of the feeds. This will then fetch the feed and display the current entries:

The final part of the application is the entry view itself. Some blogs don't provide a "full" copy of the entry via RSS, and obviously you may want to comment on the blog itself. So, at the bottom we provide a simple way to hit the real web site, as shown in the following screenshot:

Now that you've seen the application, let's build it. Once again we're going to use PhoneGap Build to create the final result, but this application will actually run as is on a regular website as well. (We will discuss exactly why in a bit.)

Creating the RSS Reader Application

Our application begins with the first page, `index.html`. This page will load in jQuery and jQuery Mobile as well. Its core mission is to list your current feeds, but it has to recognize when the user has no feeds at all and provide a bit of text encouraging them to add their first feed:

```
Listing 13-1: index.html
<!DOCTYPE html>
<html>
  <head>
    <title>RSS Reader App</title>
    <meta name="viewport" content="width=device-width, initial-
      scale=1">
    <link rel="stylesheet" href="jquery.mobile/jquery.mobile-
      1.1.0.min.css" />
    <script src="jquery.mobile/jquery-1.6.4.min.js"></script>
```

```

        <script src="jquery.mobile/jquery.mobile-1.1.0.min.js"></script>
        <script src="main.js"></script>
    </head>
    <body>
        <div data-role="page" id="intropage">
            <div data-role="header">
                <h1>RSS Reader Application</h1>
            </div>
            <div data-role="content" id="introContent">
                <p id="introContentNoFeeds" style="display:none">
                    Welcome to the RSS Reader Application. You do not currently
have
                any RSS Feeds. Please use the "Add Feed" button below to
begin.
                </p>
                <ul id="feedList" data-role="listview" data-inset="true" data-
                    split-icon="delete"></ul>
                <a href="addfeed.html" data-role="button" data-theme="b">Add
                    Feed</a>
            </div>
            <div data-role="footer">
                <h4>Created with jQuery Mobile</h4>
            </div>
        </div>
        <script>
            $("#intropage").bind("pagecreate", function(e) {
                init();
            });
        </script>
    </body>
</html>

```

As mentioned before the code listing, we need to load up our jQuery and jQuery Mobile templates first. You can see that in the beginning of the previous code listing. Most of the rest of the page is boiler-plate HTML you've seen in the previous chapter, so let's call out a few specifics.

First make note of the introductory paragraph. Notice the CSS to hide the text? The assumption here is that – most of the time – the user won't need this text as they will have feeds. Our code then is going to handle showing it when necessary.

Following that paragraph is an empty list that will display our feeds. Right below that is the button that will be used for adding new feeds.

Finally, we've got a bit of script at the end. This creates an event listener for the jQuery Mobile page event, `pagecreate`, that we tie into to then start up our application tasks.

All of our code (our custom code that is) will be stored in `main.js`. This file is a bit big, so we'll simply show parts of it that relate to each section. Please keep that in mind as we go through the chapter. The entire file can be found with the rest of the book's sample code:

Listing 13-2: Portion of `main.js`

```
function init() {  
    //handle getting and displaying the intro or feeds  
    $("#intropage").live("pageshow",function(e) {  
        displayFeeds();  
    });  
};
```

Our first snippet from `main.js` comes from the `init` function. Remember this is run on `pagecreate` for the home page. It's run before the page shows up. That makes it a good place to go ahead and register a function for when the page is displayed. We've taken most of that logic out into its own function, so let's take a look at that next.

The `displayFeeds` function

`displayFeeds` handles retrieving our feeds and displaying them. The logic is simple. If there are no feeds, we want to display the introductory text:

Listing 13-3: `displayFeeds` from `main.js`

```
function displayFeeds() {  
    var feeds = getFeeds();  
    if(feeds.length == 0) {  
        //in case we had one form before...  
        $("#feedList").html("");  
        $("#introContentNoFeeds").show();  
    } else {  
        $("#introContentNoFeeds").hide();  
        var s = "";  
        for(var i=0; i<feeds.length; i++) {  
            s+= "<li><a href='feed.html?id="+i+"' data-  
                feed='"+i+"'>"+feeds[i].name+"</a> <a href=''  
class='deleteFeed'  
                data-feedid='"+i+"'>Delete</a></li>";  
        }  
        $("#feedList").html(s);  
        $("#feedList").listview("refresh");  
    }  
}
```

Notice we also clean out the list. It's possible, a user had feeds and deleted them. By resetting the list to an empty string we ensure that we don't leave anything behind. If there are feeds, we create the list dynamically ensuring we call the `listview("refresh")` API at the end to ask jQuery Mobile to pretty up the list.

Storing our feeds

So where do the feeds come from? How do we store them? While we are using PhoneGap and could make use of the embedded SQLite database implementation, we can use something simpler – `localStorage`. `localStorage` is an HTML5 feature that allows you to store key/value pairs on the client. While you can't store complex data, you can use JSON serialization to encode complex data before it's stored. This makes storage of data extremely simple. Do keep in mind though that `localStorage` involves file storage. Your application needs to read from a file whenever a change is made to the data. Since we are talking about a simple list of feeds, though, this data should be relatively small:

Listing 13-3: `getFeeds`, `addFeed`, and `removeFeed`

```
function getFeeds() {
    if(localStorage["feeds"]) {
        return JSON.parse(localStorage["feeds"]);
    } else return [];
}
function addFeed(name,url) {
    var feeds = getFeeds();
    feeds.push({name:name,url:url});
    localStorage["feeds"] = JSON.stringify(feeds);
}
function removeFeed(id) {
    var feeds = getFeeds();
    feeds.splice(id, 1);
    localStorage["feeds"] = JSON.stringify(feeds);
    displayFeeds();
}
```

The previous three functions represent the entire wrapper to our storage system. `getFeeds` simply checks `localStorage` for the value, and if it exists, handles converting the JSON data into a native JavaScript object. `addFeed` takes a feed name and URL, creates a simple object out of it, and stores the JSON version. Finally, the `removeFeed` function simply handles finding the right item in the array, removing it, and storing it back to `localStorage`.

Adding an RSS feed

So far so good. Now let's look at the logic necessary to add a feed. If you remember, the link we used to add a feed went to `addfeed.html`. Let's take a look at it:

Listing 13-4: `addfeed.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Add Feed</title>
    <meta name="viewport" content="width=device-width, initial-
scale=1">
  </head>
  <body>
    <div data-role="page" id="addfeedpage" data-add-back-btn="true">
      <div data-role="header">
        <h1>Add Feed</h1>
      </div>
      <div data-role="content">
        <form id="addFeedForm">
          <div data-role="fieldcontain">
            <label for="feedname">Feed Name:</label>
            <input type="text" id="feedname" value="" />
          </div>
          <div data-role="fieldcontain">
            <label for="feedurl">Feed URL:</label>
            <input type="text" id="feedurl" value="" />
          </div>
          <input type="submit" value="Add Feed" data-theme="b">
        </div>
        <div data-role="footer">
          <h4>Created with jQuery Mobile</h4>
        </div>
      </div>
    </body>
  </html>
```

There isn't much to this page outside of the form. Note that our form has no action. We aren't using a server here. Instead our code is going to handle picking up the form submission and doing something with it. Also note that we've not done something we recommended earlier – putting the jQuery and jQuery Mobile includes on top. Those includes are necessary in desktop applications because it's possible the user may bookmark a page outside of your application's home page. Since the eventual target for this code is a PhoneGap application, we don't have to worry about that. This makes our HTML files a bit smaller. Now let's return to `main.js` and look at the code that handles this logic.

The following code is a snippet from the `init` method of `main.js`. It handles the button click on the form:

```
Listing 13-5: Add Feed event registration logic
//Listen for the addFeedPage so we can support adding feeds
$("#addfeedpage").live("pageshow", function(e) {
    $("#addFeedForm").submit(function(e) {
        handleAddFeed();
        return false;
    });
});
```

Now we can take a look at `handleAddFeed`. I've abstracted this code, just to make things simpler:

```
Listing 13-6: handleAddFeed
function handleAddFeed() {
    var feedname = $.trim($("#feedname").val());
    var feedurl = $.trim($("#feedurl").val());
    //basic error handling
    var errors = "";
    if(feedname == "") errors += "Feed name is required.\n";
    if(feedurl == "") errors += "Feed url is required.\n";
    if(errors != "") {
        //Create a PhoneGap notification for the error
        navigator.notification.alert(errors, function() {});
    } else {
        addFeed(feedname, feedurl);
        $.mobile.changePage("index.html");
    }
}
```

For the most part, the logic here should be simple to understand. We get the feed name and URL values, ensure they aren't blank, and optionally alert any error. If an error didn't occur, then we run the `addFeed` method described earlier. Notice we make use of the `changePage` API to return the user to the home page.

I'll call out one particular bit of code here, the line that handles displaying the error:

```
navigator.notification.alert(errors, function() {});
```

This line comes from the PhoneGap API. It creates a mobile-specific alert notification for your device. You can think of it as a fancier `JavaScript alert()` call. The second argument is a callback function for the alert window dismissal. Because we don't need to do anything in that situation, we provide an empty callback that does nothing.

Viewing a feed

Moving on – what happens when a user clicks to view a feed? This is probably the most complex aspect of the application. We begin with the HTML template, which is rather simple because most of the work is going to be done in JavaScript:

Listing 13-7: feed.html

```
<!DOCTYPE html>
<html>
  <head>
    <title>Feed</title>
    <meta name="viewport" content="width=device-width, initial-
scale=1">
  </head>
  <body>
    <div data-role="page" id="feedpage" data-add-back-btn="true">
      <div data-role="header">
        <h1></h1>
      </div>
      <div data-role="content" id="feedcontents">
      </div>
      <div data-role="footer">
        <h4>Created with jQuery Mobile</h4>
      </div>
    </div>
  </body>
</html>
```

This page basically acts as a shell. Note it has no real content at all, just empty HTML elements waiting to be filled. Let's return to `main.js` and see how this works:

Listing 13-8: Feed display handler (part 1)

```
//Listen for the Feed Page so we can displaying entries
$("#feedpage").live("pageshow", function(e) {
  //get the feed id based on query string
  var query = $(this).data("url").split("=")[1];
  //remove ?id=
  query = query.replace("?id=", "");
  //assume it's a valid ID, since this is a mobile app folks won't
  be messing with the urls, but keep
  //in mind normally this would be a concern
  var feeds = getFeeds();
  var thisFeed = feeds[query];
  $("h1",this).text(thisFeed.name);
  if(!feedCache[thisFeed.url]) {
```

```

$("#feedcontents").html("<p>Fetching data...</p>");
//now use Google Feeds API
$.get("https://ajax.googleapis.com/ajax/services/feed/
load?v=1.0&num=10&q="+encodeURIComponent(thisFeed.url)+"&callback=?", {},
function(res,code) {
    //see if the response was good...
    if(res.responseStatus == 200) {
        feedCache[thisFeed.url] = res.responseData.feed.entries;
        displayFeed( thisFeed.url);
    } else {
        var error = "<p>Sorry, but this feed could not be
        loaded:</p><p>"+res.responseDetails+"</p>";
        $("#feedcontents").html(error);
    }
}, "json");
} else {
    displayFeed(thisFeed.url);
}
});

```

This first snippet handles listening for the `pageshow` event on `feed.html`. This means it will run every time the file is viewed, which is what we want since it is used for every different feed. How does that work? Remember that our list of feeds included an identifier for the feed itself:

```

for(var i=0; i<feeds.length; i++) {
    s+= "<li><a href='feed.html?id="+i+"' data-
    feed='"+i+"'>"+feeds[i].name+"</a> <a href='' class='deleteFeed'
    data-feedid='"+i+"'>Delete</a></li>";
}

```

jQuery Mobile provides us access to the URL via the `data("url")` API. Since this returns the entire URL and we only care about stuff after the question mark, we can use some string functions to clean it up. The end result is a numeric value query, that we can use to fetch the data out of our feed query. In a regular desktop application it would be pretty simple for a user to mess with the URL parameters. Therefore, we'd do some checking here to ensure that the value requested actually exists. Since this is a single user application on a mobile device, it really isn't necessary to worry about that.

Before we try to fetch the feed, we make use of a simple caching system. The very first line in `main.js` creates an empty object:

```

//used for caching
var feedCache= {};

```

This object will store the results from our feeds so that we don't have to constantly re-fetch them. That's why the following line:

```
if(!feedCache[thisFeed.url]) {
```

is run before we do any additional network calls. So how do we actually get the feed? Google has a cool service called the Feed API (<https://developers.google.com/feed/>). It lets us use Google to handle fetching in the XML of an RSS feed and converting it to JSON. JavaScript can work with XML, but JSON is far easier since it becomes regular, simple JavaScript objects. We've got a bit of error handling, but if everything works well, we simply cache the result. The final bit is a call to `displayFeed`:

Listing 13-9: `displayFeed`

```
function displayFeed(url) {
    var entries = feedCache[url];
    var s = "<ul data-role='listview' data-inset='true'
id='entrylist'>";
    for(var i=0; i<entries.length; i++) {
        var entry = entries[i];
        s += "<li><a href='entry.html?entry="+i+"&url="+encodeURIComponent(u
rl)+"'>"+
            entry.title+"</a></li>";
    }
    s += "</ul>";
    $("#feedcontents").html(s);
    $("#entrylist").listview();
}
```

All that the previous block does is iterate over the result feed. When Google parsed the XML from the feed, it turned into an array of objects we can loop over. While there are a number of properties in the feed we may be interested in, for the list we care about the title only. Notice how we build our link. We pass the numeric index and the URL (which we will use in the next portion). This is then rendered to a simple jQuery Mobile listview.

Creating the entry view

Ready for the last part? Let's look at the individual entry display. As before, we'll begin with the template:

Listing 13-10: `entry.html`

```
<!DOCTYPE html>
<html>
  <head>
    <title>Entry</title>
```

```

    <meta name="viewport" content="width=device-width, initial-
scale=1">
  </head>
  <body>
    <div data-role="page" id="entrypage" data-add-back-btn="true">
      <div data-role="header">
        <h1></h1>
      </div>
      <div data-role="content">
        <div id="entrycontents"></div>
        <a href="" id="entrylink" data-role="button">Visit Entry</a>
      </div>
      <div data-role="footer">
        <h4>Created with jQuery Mobile</h4>
      </div>
    </div>
  </body>
</html>

```

Similar to `feed.html` before it, `entry.html` is an empty shell. Note that the header, the content, and the link are empty. All of these will be replaced with real code. Let's head back to `main.js` and look at the code that handles this page:

Listing 13-11: Entry page event handler

```

$("#entrypage").live("pageshow", function(e) {
  //get the entry id and url based on query string
  var query = $(this).data("url").split("?")[1];
  //remove ?
  query = query.replace("?", "");
  //split by &
  var parts = query.split("&");
  var entryid = parts[0].split("=")[1];
  var url = parts[1].split("=")[1];
  var entry = feedCache[url][entryid];
  $("#h1", this).text(entry.title);
  $("#entrycontents", this).html(entry.content);
  $("#entrylink", this).attr("href", entry.link);
});

```

So what's going on here? Remember that we passed an index value (which entry was clicked, the first, the second?) and the URL of the feed. We parse out those values from the URL. Once we know the URL of the feed, we can use our cache to get the specific entry. Once we have that, it's a simple matter to update the header, contents, and link. And that's it!

Going further

You can take the code from this application and upload it to the PhoneGap Build service now to try it out on your own device. But what else could we have done? Here's a short list of things to consider:

- PhoneGap provides a connection API (http://docs.phonegap.com/en/1.4.1/phonegap_connection_connection.md.html) that returns information about the device's connection status. You could add support for this to prevent the user from trying to read a feed when the device isn't online.
- While we store the user's feeds in `localStorage`, the cached data from reading the RSS entry is stored temporarily. You could also store that data and use it when the user is offline.
- PhoneGap has an excellent plugin API and a great variety of plugins are already available. (<https://github.com/phonegap/phonegap-plugins>) One of these plugins allow for easier sending of SMS messages. You could add an option to send an entry title and link to a friend via SMS. Did we mention PhoneGap also lets you work with your contacts? See the Contacts API for more information: http://docs.phonegap.com/en/1.4.1/phonegap_contacts_contacts.md.html.

Hopefully you get the idea. This is only one example of the power of jQuery Mobile and PhoneGap.

Summary

In this chapter, we took what we had learned of PhoneGap from the previous chapter and created a full, if rather simple, mobile application making use of jQuery Mobile for design and interactivity.

Thank you for buying **jQuery Mobile Web Development Essentials**

About Packt Publishing

Packt, pronounced 'packed', published its first book "*Mastering phpMyAdmin for Effective MySQL Management*" in April 2004 and subsequently continued to specialize in publishing highly focused books on specific technologies and solutions.

Our books and publications share the experiences of your fellow IT professionals in adapting and customizing today's systems, applications, and frameworks. Our solution based books give you the knowledge and power to customize the software and technologies you're using to get the job done. Packt books are more specific and less general than the IT books you have seen in the past. Our unique business model allows us to bring you more focused information, giving you more of what you need to know, and less of what you don't.

Packt is a modern, yet unique publishing company, which focuses on producing quality, cutting-edge books for communities of developers, administrators, and newbies alike. For more information, please visit our website: www.packtpub.com.

About Packt Open Source

In 2010, Packt launched two new brands, Packt Open Source and Packt Enterprise, in order to continue its focus on specialization. This book is part of the Packt Open Source brand, home to books published on software built around Open Source licences, and offering information to anybody from advanced developers to budding web designers. The Open Source brand also runs Packt's Open Source Royalty Scheme, by which Packt gives a royalty to each Open Source project about whose software a book is sold.

Writing for Packt

We welcome all inquiries from people who are interested in authoring. Book proposals should be sent to author@packtpub.com. If your book idea is still at an early stage and you would like to discuss it first before writing a formal book proposal, contact us; one of our commissioning editors will get in touch with you.

We're not just looking for published authors; if you have strong technical skills but no writing experience, our experienced editors can help you develop a writing career, or simply get some additional reward for your expertise.

jQuery Mobile First Look

ISBN: 978-1-84951-590-0

Paperback: 216 pages

Discover the endless possibilities offered by jQuery Mobile for rapid mobile web development

1. Easily create your mobile web applications from scratch with jQuery Mobile
2. Learn the important elements of the framework and mobile web development best practices
3. Customize elements and widgets to match your desired style
4. Step-by-step instructions on how to use jQuery Mobile

PhoneGap Beginner's Guide

ISBN: 978-1-84951-536-8

Paperback: 328 pages

Build cross-platform mobile applications with the PhoneGap open source development framework

1. Learn how to use the PhoneGap mobile application framework
2. Develop cross-platform code for iOS, Android, BlackBerry, and more
3. Write robust and extensible JavaScript code
4. Master new HTML5 and CSS3 APIs
5. Full of practical tutorials to get you writing code right away

Please check www.PacktPub.com for information on our titles

Sencha Touch Mobile JavaScript Framework

ISBN: 978-1-84951-510-8

Paperback: 316 pages

Build web applications for Apple iOS and Google Android touchscreen devices with this first HTML5 mobile framework

1. Learn to develop web applications that look and feel native on Apple iOS and Google Android touchscreen devices using Sencha Touch through examples
2. Design resolution-independent and graphical representations like buttons, icons, and tabs of unparalleled flexibility
3. Add custom events like tap, double tap, swipe, tap and hold, pinch, and rotate

Android Application Testing Guide

ISBN: 978-1-84951-350-0

Paperback: 332 pages

Build intensively tested and bug free Android applications

1. The first and only book that focuses on testing Android applications
2. Step-by-step approach clearly explaining the most efficient testing methodologies
3. Real world examples with practical test cases that you can reuse

Please check www.PacktPub.com for information on our titles
